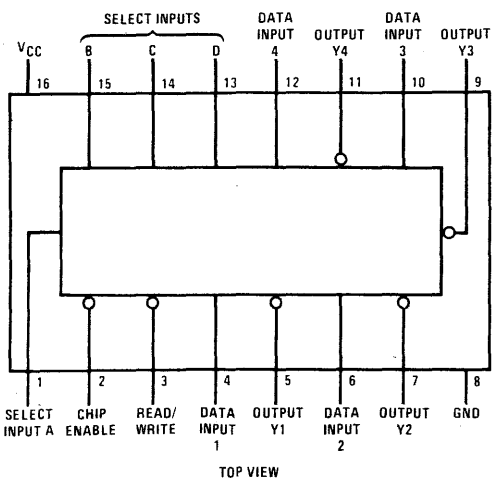
DM54LS189/DM74LS189 low power 64-bit random access memories with TRI-STATE® outputs

general description

These 64-bit active-element memories are monolithic Schottky-clamped transistor-transistor logic (TTL) arrays organized as 16 words of 4 bits each. They are fully decoded and feature a chip enable input to simplify decoding required to achieve the desired system organization. This device is implemented with low power Schottky technology resulting in one-fifth power while retaining the speed of standard TTL.

The TRI-STATE output combines the convenience of an open-collector with the speed of a totem-pole output; it can be bus-connected to other similar outputs, yet it retains the fast rise time characteristics of the TTL totem-pole output. Systems utilizing data bus lines with a defined pull-up impedance can employ the open-collector DM54LS289.

Write Cycle: The complement of the information at the data input is written into the selected location when both the chip enable input and the read/write input are low. While the read/write input is low, the outputs are in the high impedance state. When a number of the DM54LS189 outputs are bus-connected, this high impedance state will neither load nor drive the bus line, but it will allow the bus line to be driven by another active output or a passive pull-up if desired.



Read Cycle: The stored information (complement of information applied at the data inputs during the write cycle) is available at the outputs when the read/write input is high and the chip enable is low. When the chip enable input is high, the outputs will be in the high impedance state.

features

- Schottky-clamped for high speed applications
  - Access from chip enable input—40 ns typ
  - Access from address inputs—60 ns typ
- TRI-STATE outputs drive bus-organized systems and/or high capacitive loads
- Low power—75 mW typ
- DM54LS189 is guaranteed for operation over the full military temperature range of −55°C to +125°C
- Compatible with most TTL and DTL logic circuits
- Chip enable input simplifies system decoding

Bipolar RAMs

DM54S189/DM74S189 64-bit random access memories with TRI-STATE® outputs

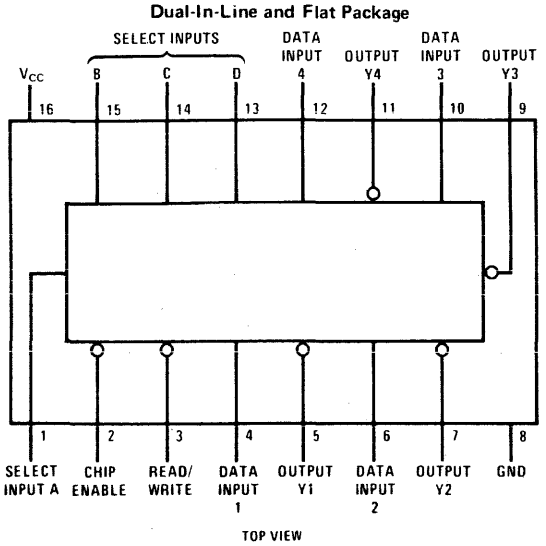
general description

These 64-bit active-element memories are monolithic Schottky-clamped transistor-transistor logic (TTL) arrays organized as 16 words of four-bits each. They are fully decoded and feature a chip-enable input to simplify decoding required to achieve the desired system organization. The memories feature PNP input transistors that reduce the low level input current requirement to a maximum of −0.25 mA, only one-eighth that of a DM54S/DM74S standard load factor. The chip-enable circuitry is implemented with minimal delay times to compensate for added system decoding.

The TRI-STATE output combines the convenience of an open-collector with the speed of a totem-pole output; it can be bus-connected to other similar outputs, yet it retains the fast-rise-time characteristics of the TTL totem-pole output. Systems utilizing data-bus lines with a defined pull-up impedance can employ the open-collector DM54S289.

Write Cycle: The complement of the information at the data input is written into the selected location when both the chip-enable input and the read/write input are low. While the read/write input is low, the outputs are in the high-impedance state. When a number of the DM54S189 outputs are bus-connected, this high-impedance state will neither load nor drive the bus line, but it will allow the bus line to be driven by another active output or a passive pull-up if desired.

Read Cycle: The stored information (complement of information applied at the data inputs during the write cycle) is available at the outputs when the read/write input is high and the chip-enable is low. When the chip-enable input is high, the outputs will be in the high-impedance state.



The fast access time of the DM54S189 makes it particularly attractive for implementing high-performance memory functions requiring access times on the order of 25 ns. The high capacitive-drive capability of the outputs permits expansion without additional output buffering. The unique functional capability of the DM54S189 outputs being at a high impedance during writing combined with the data inputs being inhibited during reading means that both data inputs and outputs can be connected to the data lines of a bus-organized system without the need for interface circuits.

features

- Schottky-clamped for high-speed applications:
  - access from chip-enable input 12 ns typ
  - access from address inputs 25 ns typ
- TRI-STATE outputs drive bus-organized systems and/or high capacitive loads
- DM54S289, DM74S289 are functionally equivalent, have open-collector outputs, and are compatible with Intel 3101A in most applications
- DM54S189 is guaranteed for operation over the full military temperature range of −55°C to +125°C
- Compatible with most TTL and DTL logic circuits
- Chip-enable input simplifies system decoding

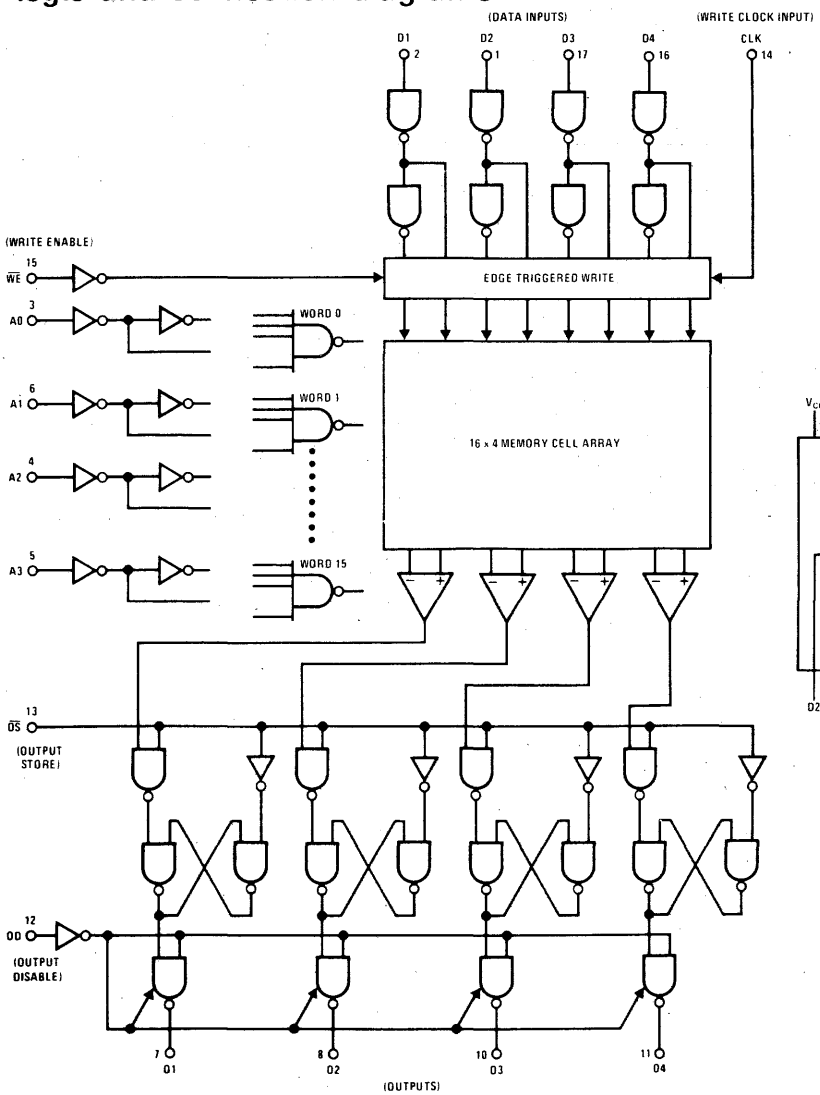
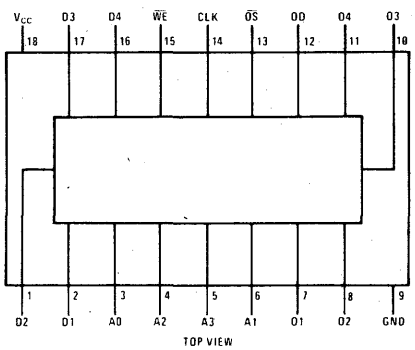
DM75S68/DM85S68 64-bit (16×4) edge triggered register

general description



The DM75S68/DM85S68 is an addressable "D" register file. Any of its 16 four-bit words may be asynchronously read or may be written into on the next clock transition. An input terminal is provided to enable or disable the synchronous writing of the input data into the location specified by the address terminals. An output disable terminal operates only as a TRI-STATE® output control terminal. The addressable register data may be latched at the outputs and retained as long as the output store terminal is held in a low state. This memory storage condition is independent of the state of the output disable terminal.

All input terminals are high impedance at all times, and all outputs have low impedance active drive logic states and the high impedance TRI-STATE condition.



features

- On chip output register
- Edge triggered write
- High speed — 30 ns typ
- TRI-STATE output
- Optimized for register stack applications
- Typical power dissipation — 350 mW
- 18-pin package

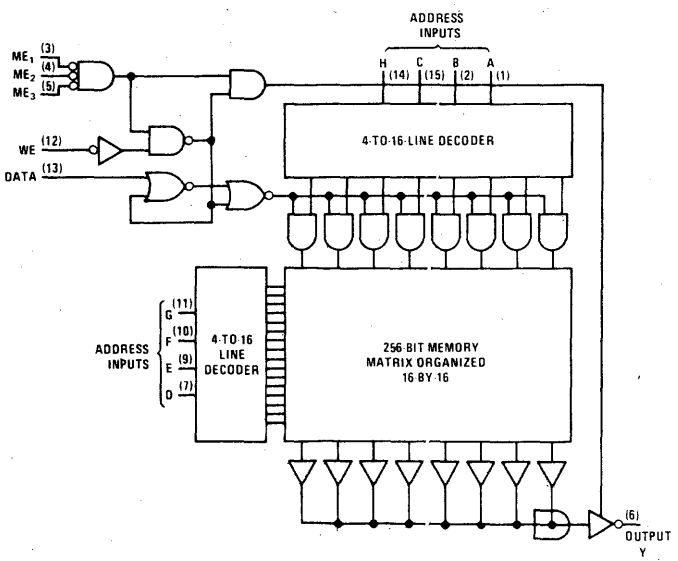
DM54S206/DM74S206 256-bit read/write schottky memories with open-collector outputs

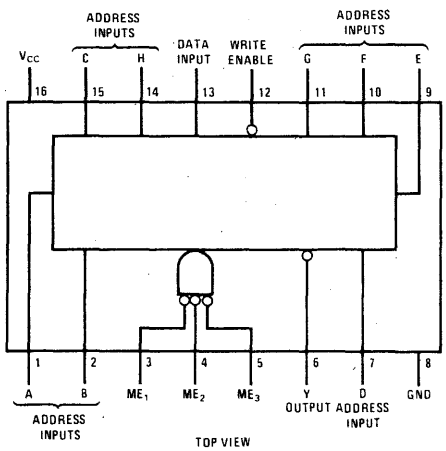
general description

The DM54S206/DM74S206 256-bit active-element memories are monolithic transistor-transistor logic (TTL) integrated circuits organized as 256 words of one bit each. They are fully decoded and have three gated memory-enable inputs to simplify decoding required to achieve the desired system organization. The memories feature PNP input transistors which reduce the low-level input current requirement to a maximum of −0.25 milliamperes, only one-eighth that of a normalized Series 54S/74S load factor. The memory-enable circuitry is implemented with minimal delay times to compensate for added system decoding.



Write Cycle: The complement of the information at the data input is written into the selected location when all memory-enable inputs and write-enable input are low. While the write-enable input is low, the output is off.

Read Cycle: The stored information (complement of information applied at the data input during the write cycle) is available at the output when the write-enable input is high and the three memory-enable inputs are low. When any one of the memory enable inputs is high, the output will be off.



features

- Schottky-clamped for high-speed memory systems:
  - Access from memory-enable inputs 17 ns typ
  - Access from address inputs 35 ns typ
  - Power dissipation 1.4 mW/bit typ
- Open-collector output for word expansion
- Fully decoded, organized as 256 words of one bit each
- Compatible with most TTL and DTL logic circuits
- Multiple memory-enable inputs to minimize external decoding

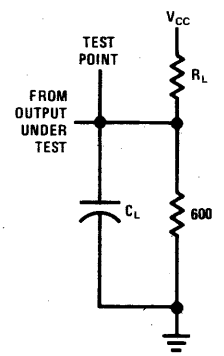
Enable Time from Memory Enable (t_{PHL})			13	35		13	25	ns
Disable Time from Write Enable (t_{PLH})			20	50		20	40	ns
Sense-Recovery Time (t_{SR})			14	50		14	40	ns

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: Unless otherwise specified min/max limits apply across the −55°C to +125°C temperature range for DM54S206 and across the 0°C to +70°C range for the DM74S206. All typicals are given for V_{CC} = 5.0V and T_A = +25°C.

Note 3: All voltage values are with respect to network ground terminal.

Note 4: I_{CC} is measured with the write enable and memory enable inputs grounded, all other inputs at 4.5V, and the output open.



truth table

FUNCTION	INPUTS		OUTPUT
	MEMORY ENABLE†	WRITE ENABLE	
Write (Store Complement of Data)	L	L	H
Read	L	H	Stored Data
Inhibit	H	X	H

H = high level, L = low level, X = irrelevant

†For memory enable: L = all ME inputs low; H = one or more ME inputs high.

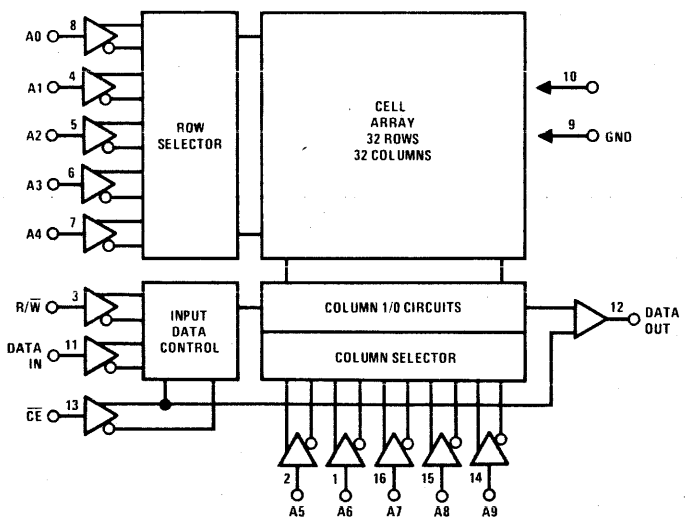
ac test circuit

C_L includes probe and jig capacitance.

MM2102A, MM2102AL family
1024-bit (1024 × 1) static random access memories

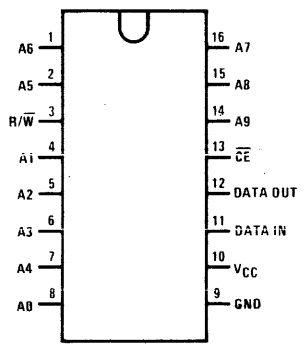
general description

The MM2102A family of high speed 1024 x 1-bit static random access read/write memories are manufactured using N-channel depletion-mode silicon gate technology. Static storage cells eliminate the need for clocks or refresh circuitry and the resultant cost associated with them.



Low threshold silicon gate N-channel technology allows complete DTL/TTL compatibility of all inputs and outputs as well as a single 5V supply. The separate chip enable input ($\overline{CE}$) controlling the TRI-STATE® output allows easy memory expansion by OR-tying individual devices to a data bus. Data in and data out have the same polarity.

In addition to the MM2102A, a low power version, the MM2102AL, is also available. This selection offers a maximum operating current of 33 mA and a guaranteed standby mode down to a power supply voltage of 1.5V.



features

- Single 5V supply
- All inputs and outputs directly DTL/TTL compatible
- Static operation—no clocks or refresh
- TRI-STATE output for bus interface
- All inputs protected against static charge
- Access time down to 250 ns

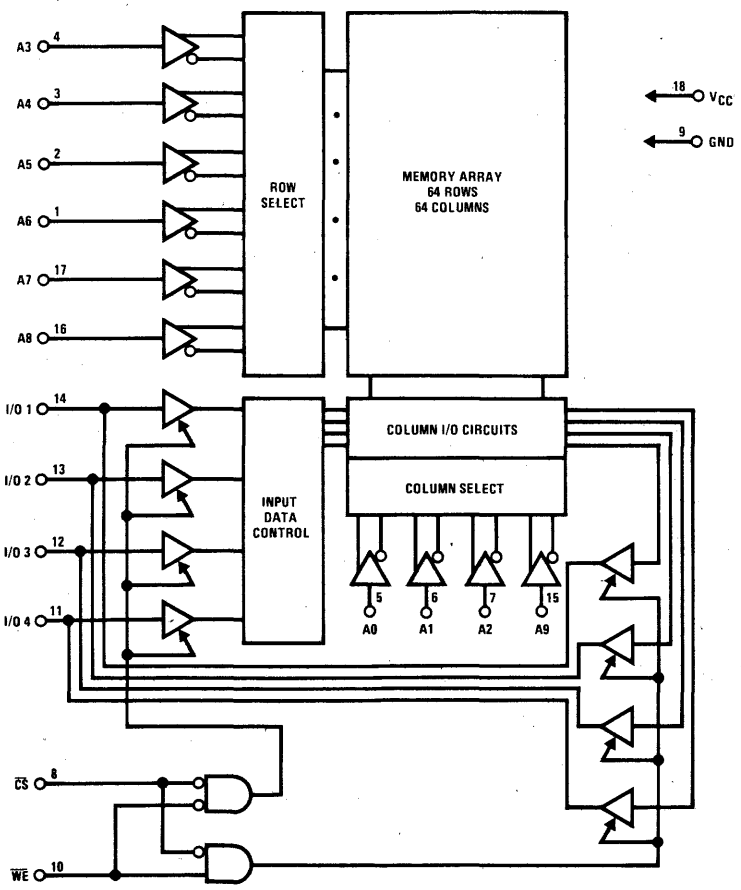
MM2114L Family
4096-Bit (1024 x 4) Static Random Access Memories

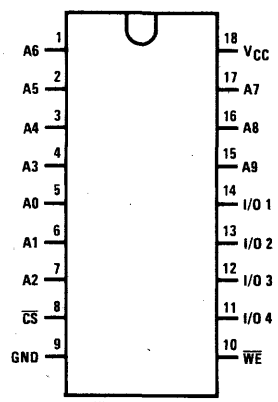
General Description



The MM2114L family of high speed 1024 x 4-bit static random access read/write memories are manufactured using N-channel depletion-mode silicon gate technology. Static storage cells eliminate the need for clocks or refresh circuitry and the resultant cost associated with them.

Low threshold silicon gate N-channel technology allows complete DTL/TTL compatibility of all inputs and outputs as well as a single 5V supply. The separate chip select input ($\overline{CS}$) controlling the TRI-STATE® output allows easy memory expansion by OR-tying individual devices to a data bus. Data in and data out have the same polarity.

Features



- Single 5V supply
- All inputs and outputs directly DTL/TTL compatible
- Static operation—no clocks or refresh
- TRI-STATE output for bus interface
- All inputs protected against static charge
- Access time down to 250 ns

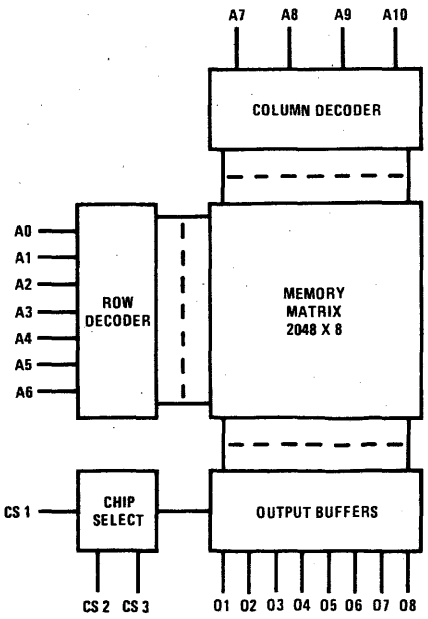
MM2316E 16,384-Bit Read Only Memory

general description

The MM2316E is a static MOS 16,384-bit read-only memory organized in a 2048-word-by-8-bit format. It is fabricated using N-channel enhancement and depletion-mode silicon-gate technology which provides complete DTL/TTL compatibility and single power-supply operation.

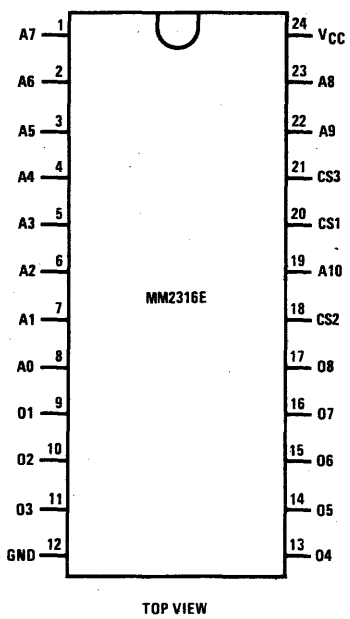
Three programmable chip selects controlling the TRI-STATE® outputs allow for memory expansion.

Programming of the memory array and chip-select active levels is accomplished by changing one mask during fabrication.



features

- Fully decoded
- Single 5V power supply
- Inputs and outputs TTL compatible
- Static operation
- TRI-STATE outputs for bus interface
- Programmable chip selects
- 2048 word by 8-bit organization
- Maximum access time—450 ns



applications

- Microprogramming
- Control logic
- Table look-up

custom ROM programming

Custom ROM programs are submitted to National in three formats: paper tape, punched cards or truth table, with punched cards being the preferred. These programs are converted into machine language and outputted on a magnetic tape. This magnetic tape is used to make the programmable mask and the test tape. The wafers are tested at the wafer level. The wafer is then scribed and the good dice assembled. After assembly, the units are tested using the custom test tape to assure the correct output pattern for every address.

National has programs to convert NEGATIVE logic to POSITIVE or POSITIVE to NEGATIVE so ROMs can be entered in either logic, but the customer must specify which logic definition is used.

PROGRAMMING DEFINITIONS

Logic Definitions

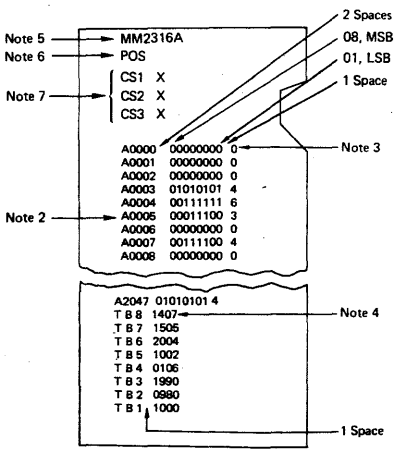
NEGATIVE Logic: "0" = V_H = the more positive voltage. "1" = V_L = the more negative voltage.

POSITIVE Logic: "0" = V_L = the more negative voltage. "1" = V_H = the more positive voltage.

Input/Output Definitions

Address: A0 is the least significant input address.

Outputs: O1 is the least significant output.



Custom ROM Programming

INFORMATION NEEDED

So that National can better serve its customers, the following information *must* be submitted with each ROM code.

National Semiconductor Corporation 2900 Semiconductor Dr., Santa Clara, CA 95051 Phone (408) 737-5000 TWX 910-339-9240			NATIONAL PART NUMBER

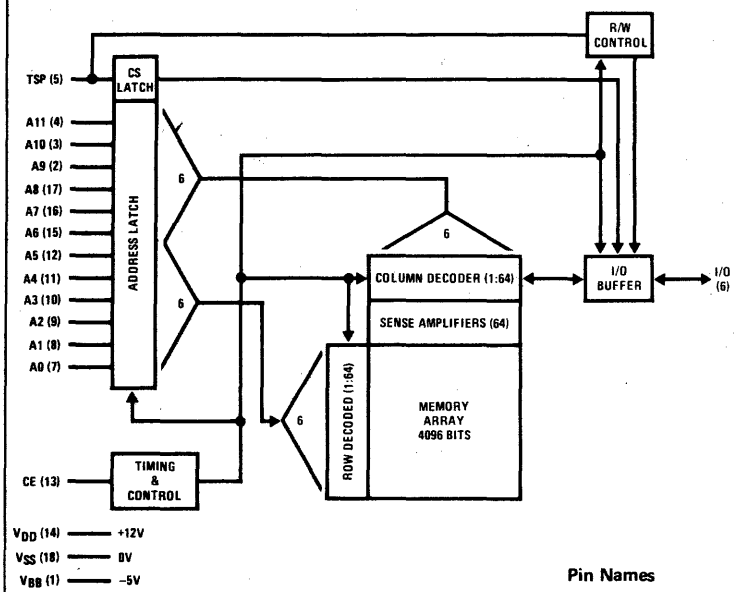
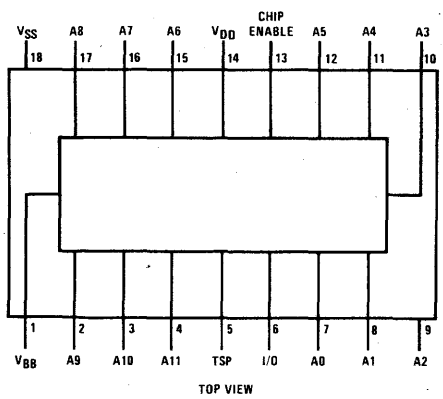
MM4270 TRI-SHARE™ extended temperature range 4096-bit dynamic random access read/write memory

general description



The MM4270 is a 4096-bit dynamic random access memory with TRI-SHARE. Because of this unique design feature, National is able to package a 4k device in an 18-pin dual-in-line package. The device is manufactured using N-channel silicon gate technology with a single transistor cell which provides higher density on a monolithic chip and thus lower cost.

The TRI-SHARE Port (TSP) is a multifunction input that, along with a common input/output, allows National to manufacture an 18-pin version of a 4k RAM. The functions controlled by the TSP are read/write, V_{CC}, and logical chip select. In order to understand how the TSP works, consider the timing diagrams. The state of the TSP at the leading edge of the chip enable clock determines whether the device is selected. If it is at a TTL high level, the chip is selected and the device goes into a read mode after chip enable goes high. This high level also performs a V_{CC} function in that it enables a reference voltage for a TTL high output. The supply for the output buffer is V_{DD}, not the TRI-SHARE Port; thus, no special driver is required. In order to perform a write, the TSP must be pulsed low after the minimum hold time and the appropriate data placed on the I/O. When the MM4270 goes into write, the output circuit is disabled. If the TSP is low at the start of the cycle, the memory is not selected but it will be refreshed if the chip enable clock is pulsed.



features

- 4096 x 1 bit organization
- Access time 270 ns maximum
- Cycle time 470 ns minimum
- TRI-SHARE port
- High memory density—18-pin package
- TTL compatible inputs (except chip enable)
- TRI-STATE® common input/output
- Registers on chip for addresses and chip select
- Two power supplies, +12V, −5V
- Simple read-modify-write operation

V_{IL}	Input Low Voltage	t_T = 20 ns, *(Figure 4)*	−1.0		0.6	V
V_{IH}	Input High Voltage		2.2		V_{CC}+1	V
V_{ILC}	CE Input Low Voltage		−1.0		1.0	V
V_{IHC}	CE Input High Voltage		V_{DD}−1		V_{DD}+1	V
V_{OL}	Output Low Voltage	I_{OL} = 2.0 mA	0.0		0.45	V
V_{OH}	Output High Voltage	I_{OH} = −2.0 mA	2.4			V

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: The only requirement for the sequence of applying voltage to the device is that V_{DD} or V_{SS} should never be 0.3V more negative than V_{BB}.

Note 3: Typical values are for T_A = 25°C and nominal power supply voltages.

Note 4: The I_{DD} current is to V_{SS}. The I_{BB} current is the sum of all leakage currents.

ac electrical characteristics T_A = −55°C to +85°C, V_{DD} = 12V ±5%, V_{BB} = −5V ±10%

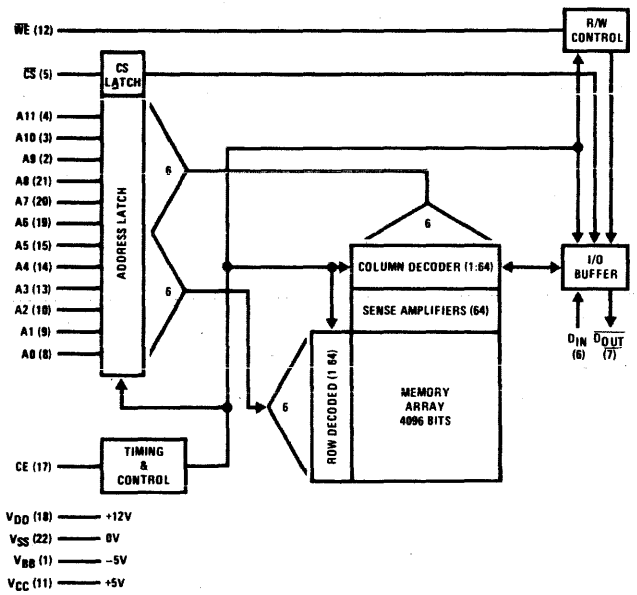
MM4280 4096-bit dynamic random access read/write memory with extended temperature range

general description

National's MM4280 is a 4096 word by 1 bit dynamic RAM. It incorporates the latest memory design features and can be used in a wide variety of applications, from those which require very high speed to ones where low cost and large bit capacity are the prime criteria.

The MM4280 must be refreshed every 1 ms. This can be accomplished by performing a read cycle at each of the 64 row addresses (A0–A5). The chip select input can be either high or low for refresh. Addresses (A6–A11) must have a stable address during the refresh cycle. Any address is satisfactory as long as the address set-up and hold times are met. The chip select input can be either high or low for refresh.



The MM4280 has been designed with minimum production costs as a prime criterion. It is fabricated using N-channel silicon gate MOS technology, which is an ideal choice for high density integrated circuits. The MM4280 uses a single transistor cell to minimize the device area.

The single device cell, along with unique design features in the on-chip peripheral circuits, yields a high performance memory device.

features

- Extended temperature range: −55°C to +85°C
- Organization: 4096 x 1
- Access time 270 ns maximum
- Cycle time 470 ns minimum
- Easy system interface
  - One high voltage input—chip enable
  - TTL compatible—all other inputs and outputs
- Address registers on-chip
- TRI-STATE® output
- Simple read-modify-write operation
- Industry standard pin configuration

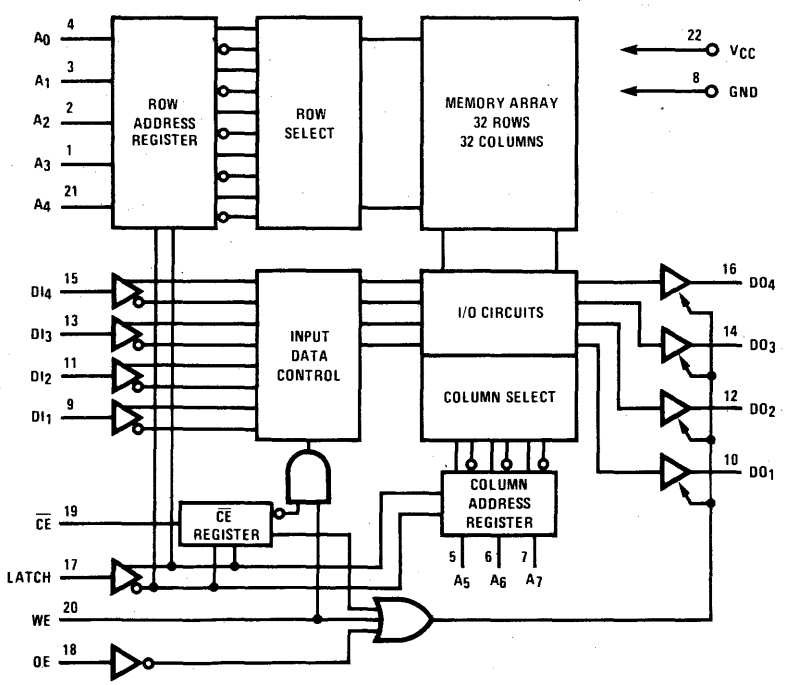
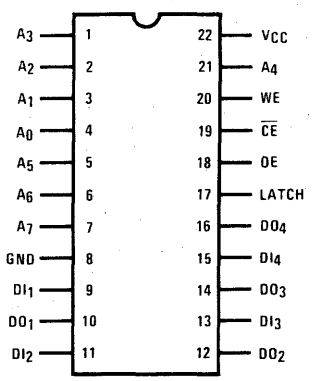
MM5269 1024-bit (256 × 4) fully decoded static RAM with on chip registers

general description

The National MM5269 is a 256 word x 4 bit Static Random Access Memory device fabricated using N-Channel enhancement mode Silicon Gate technology. Static storage cells eliminate the need for refresh and the additional peripheral circuitry associated with refresh. Data in and data out have the same polarity.



The MM5269 is fully TTL compatible including inputs, outputs and power supply. The chip enable input allows memory expansion and the address latch feature eliminates the need for external address registers. The output enable is provided for systems which use a common input/output data bus. All of the features of this memory device can be combined to make a low cost, high performance and easy to manufacture memory system. System design costs are also minimized because of the ease-of-use of the MM5269.



National's Silicon Gate process provides protection against contamination and permits the use of low cost Epoxy B packaging.

features

- Organization 256 Words by 4 Bits
- Access Time – 0.5 to 1.0 μs
- On Chip Address and Chip Enable Registers
- Directly TTL Compatible – All Inputs and Outputs
- Single +5 V Power Supply
- Tri-State ® Output – OR-Tie Capability
- Output Enable for Common Data Bus Systems
- Static Memory – No Refresh Required
- Packaged in a 22 Pin Epoxy B Dual-In-Line

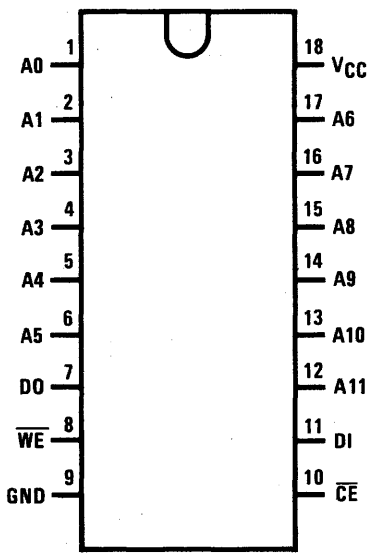
MM5257 4096x1 Static Random Access Memory

General Description

The MM5257 is a 4096 word by 1-bit static random access memory fabricated using N-channel silicon-gate technology. All internal circuits are fully static and therefore require no clocks or refreshing for operation. The data is read out nondestructively and has the same polarity as the input data.

The separate chip enable input ($\overline{CE}$) controlling the TRI-STATE® output allows easy memory expansion by OR-tying individual devices to a data bus.



The output is held in a high impedance state during write to simplify common I/O applications.

Features

- All inputs and outputs directly TTL compatible
- Static operation—no clocks or refreshing required
- Low power—200 mW typical
- High speed—250 ns typical
- TRI-STATE output for bus interface
- Separate Data In and Data Out pins
- Single +5V supply
- Standard 18-pin dual-in-line package

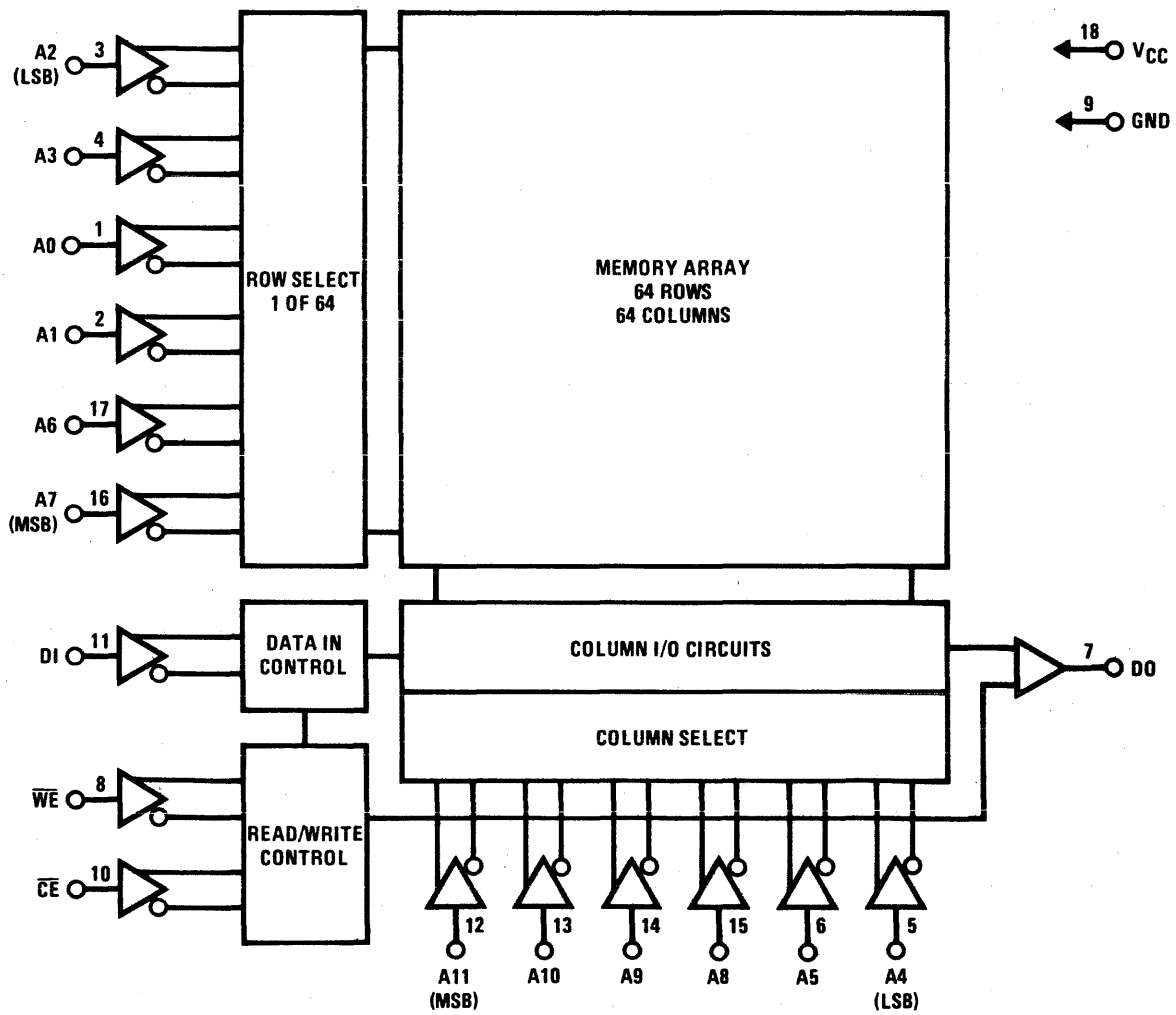
Functional Description

Two pins control the operation of the MM5257. Chip Enable ($\overline{CE}$) enables write and read operations and controls TRI-STATING of the data-output buffer. Write Enable ($\overline{WE}$) chooses between READ and WRITE modes and also controls output TRI-STATING. The truth table details the states produced by combinations of the $\overline{CE}$ and $\overline{WE}$ controls.

READ-cycle timing is shown in the section on Switching Time Waveforms. $\overline{WE}$ is kept high. Independent of $\overline{CE}$, any change in address code causes new data to be fetched and brought to the output buffer. $\overline{CE}$ must be low, however, for the output buffer to be enabled and transfer the data to the output pin.



Address access time, t_A, is the time required for an address change to produce new data at the output pin, assuming $\overline{CE}$ has enabled the output buffer prior to data arrival. Chip Enable-to-output delay, t_{CO}, is the time required for $\overline{CE}$ to enable the output buffer and transfer previously fetched data to the output pin. Operation with $\overline{CE}$ continuously held low is permissible.

WRITE-cycle timing is shown in the section on Switching Time Waveforms. Writing occurs only during the time both $\overline{CE}$ and $\overline{WE}$ are low. Minimum write-pulse width, t_{WP}, refers to this simultaneous low region. Data set-up and hold times are measured with respect to whichever control first rises. Successive write operations may be performed with $\overline{CE}$ continuously held low. $\overline{WE}$ then is used to terminate WRITE between address changes. Alternatively, $\overline{WE}$ may be held low for successive WRITES and $\overline{CE}$ used for WRITE interruption between address change.

In any event, either $\overline{WE}$ or $\overline{CE}$ (or both) must be high during address transitions to prevent erroneous WRITE.

Stand-by operation allows data to be maintained with approximately 50% less operating current. The 2 requirements to guarantee data retention are: a) the power supply voltage must meet the condition $V_{CC} \geq 1.5V$, and b) $\overline{CE}$ must be controlled; to disable the chip prior to reducing V_{CC}, to keep it disabled during the time V_{CC} is reduced, and to maintain the disabled state long enough after V_{CC} is increased to normal for the chip to recover. These requirements are shown by the stand-by waveforms and characteristics.

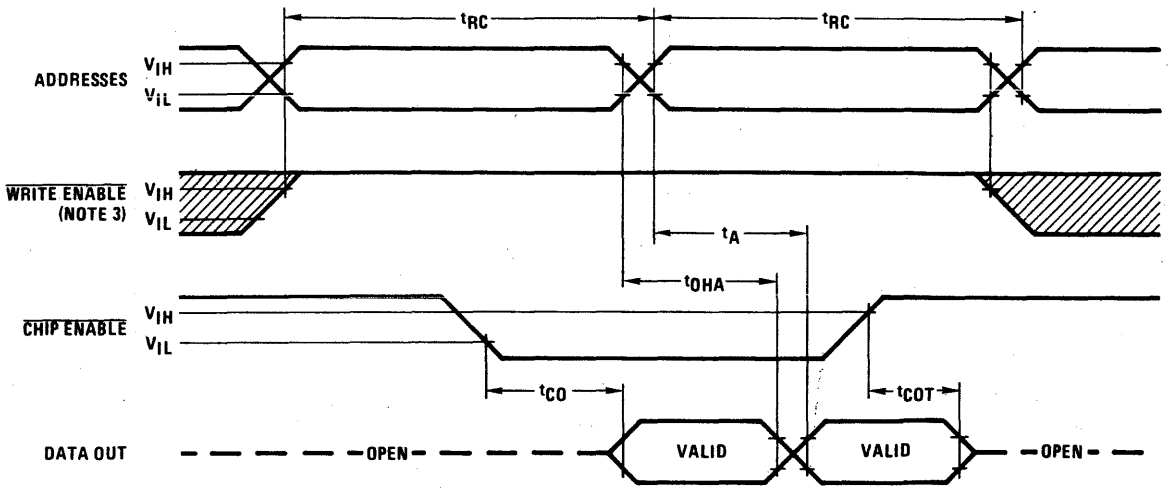
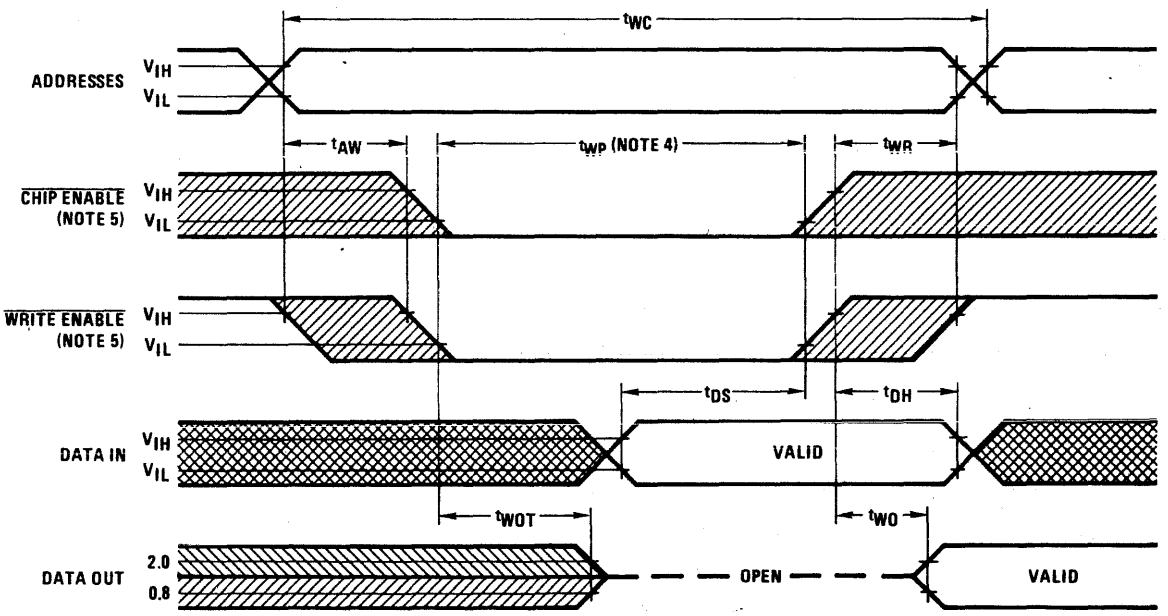
V_{IL}	Logical "0" Input Voltage		−0.5		0.8	V
V_{OH}	Logical "1" Output Voltage	$I_{OH} = -200\ \mu A$	2.4			V
V_{OL}	Logical "0" Output Voltage	$I_{OL} = 2.1$ mA			0.4	V
I_{LI}	Input Load Current	$V_{IN} = 0$ to 5.25V	−10		10	μA
I_{LO}	Output Leakage Current	$V_O = 4V$ to 0.4V, $\overline{CE} = V_{IH}$	−10		10	μA
I_{CC}	Power Supply Current	All Inputs = 5.25V		35		mA

AC Electrical Characteristics $T_A = 0°C$ to $+70°C$, $V_{CC} = 5V \pm 5\%$, (Note 2)



SYMBOL	PARAMETER	CONDITIONS	MIN	TYP (Note 1)	MAX	UNITS
READ CYCLE						
t_{RC}	Read Cycle Time	$\overline{WE} = V_{IH}$		250		ns
t_A	Access Time			250		ns
t_{CO}	Chip Enable to Output Valid			85		ns
t_{COT}	Chip Enable to Output TRI-STATE			60		ns
t_{OHA}	Output Hold from Address Change			100		ns
WRITE CYCLE						
t_{WC}	Write Cycle Time			250		ns
t_{AW}	Address to Write Set-Up Time			0		ns
t_{WP}	Write Pulse Width			200		ns
t_{WR}	Write Recovery Time			0		ns
t_{DS}	Data Set-Up Time			85		ns
t_{DH}	Data Hold Time			0		ns
t_{WOT}	Write Enable to Output TRI-STATE			80		ns
t_{WO}	Write Enable to Output Valid			70		ns

Note 1: Typical values at $T_A = 25°C$.



Note 2: All input transitions $\leq$ 10 ns. Timing referenced to $V_{IL(MAX)}$ or $V_{IH(MIN)}$ for inputs, 0.8V and 2V for output. For test purposes, input levels should swing between 0V and 3V. Output load = 1 TTL gate and $C_L = 50$ pF.

Switching Time Waveforms

Read Cycle

Write Cycle

Note 3: $\overline{WE}$ is high during a read cycle ($\overline{WE} \geq V_{IH(MIN)}$).

Note 4: t_{WP} defines the period when both $\overline{CE}$ and $\overline{WE}$ are low. t_{AW} is referenced to the later of $\overline{CE}$ or $\overline{WE}$ going low while t_{DS}, t_{DH} and t_{WR} are referenced to the earlier of $\overline{CE}$ or $\overline{WE}$ going high. t_{WOT} and t_{WO} are referenced to $\overline{WE}$ with $\overline{CE}$ low.

Note 5: Either $\overline{WE}$ or $\overline{CE}$ (or both) must be high during address transitions to prevent erroneous write.

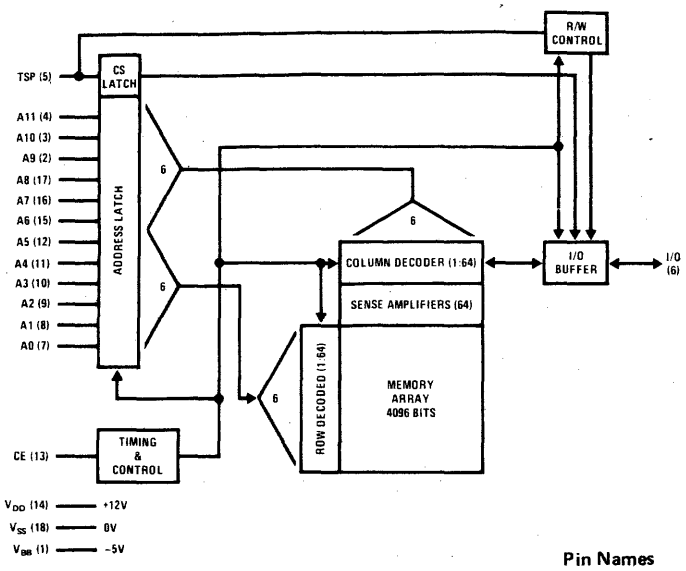
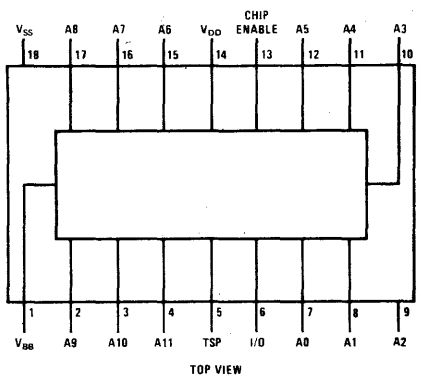
MM5270 TRI-SHARE™ 4096-bit fully decoded dynamic random access read/write memory

general description



The MM5270 is a 4096-bit dynamic random access memory with TRI-SHARE. Because of this unique design feature, National is able to package a 4k device in an 18-pin dual-in-line package. The device is manufactured using N-channel silicon gate technology with a single transistor cell which provides higher density on a monolithic chip and thus lower cost.

The TRI-SHARE Port (TSP) is a multifunction input that, along with a common input/output, allows National to manufacture an 18-pin version of a 4k RAM. The functions controlled by the TSP are read/write, V_{CC}, and logical chip select. In order to understand how the TSP works, consider the timing diagrams. The state of the TSP at the leading edge of the chip enable clock determines whether the device is selected. If it is at a TTL high level, the chip is selected and the device goes into a read mode after chip enable goes high. This high level also performs a V_{CC} function in that it enables a reference voltage for a TTL high output. The supply for the output buffer is V_{DD}, not the TRI-SHARE Port; thus, no special driver is required. In order to perform a write, the TSP must be pulsed low after the minimum hold time and the appropriate data placed on the I/O. When the MM5270 goes into write, the output circuit is disabled. If the TSP is low at the start of the cycle, the memory is not selected but it will be refreshed if the chip enable clock is pulsed.



features

- 4096 x 1 bit organization
- Access time 200 ns maximum
- Cycle time 400 ns minimum
- TRI-SHARE port
- High memory density—18-pin package
- TTL compatible inputs (except chip enable)
- TRI-STATE® common input/output
- Registers on chip for addresses and chip select
- Two power supplies, +12V, −5V
- Simple read-modify-write operation

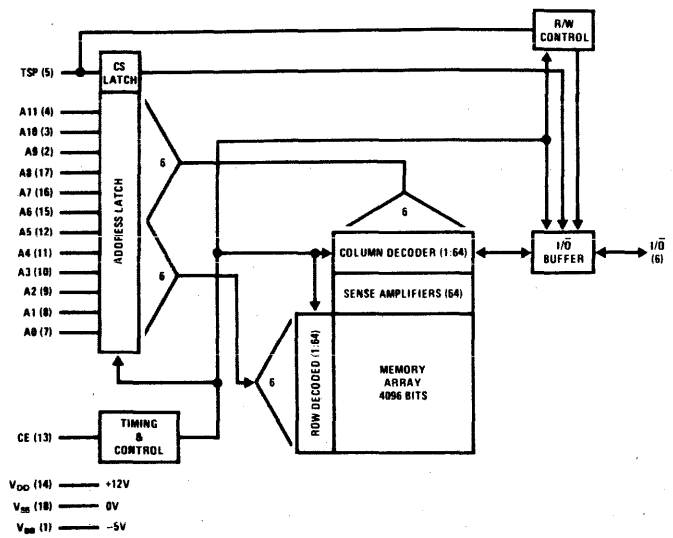
MM5270A TRI-SHARE™ 4096-bit fully decoded dynamic random access read/write memory

general description

The MM5270A is a 4096-bit dynamic random access memory with TRI-SHARE. Because of this unique design feature, National is able to package a 4k device in an 18-pin dual-in-line package. The device is manufactured using N-channel silicon gate technology with a single transistor cell which provides higher density on a monolithic chip and thus lower cost.

The TRI-SHARE Port (TSP) is a multifunction input that, along with a common input/output, allows National to manufacture an 18-pin version of a 4k RAM. The functions controlled by the TSP are read/write, V_{CC}, and logical chip select. In order to understand how the TSP works, consider the timing diagrams. The state of the TSP at the leading edge of the chip enable clock determines whether the device is selected. If it is at a TTL high level, the chip is selected and the device goes into a read mode after chip enable goes high. This high level also enables a reference voltage for a TTL high output. The supply for the output buffer is V_{DD}, not the TRI-SHARE Port; thus, no special driver is required. In order to perform a write, the TSP must be pulsed low after the minimum hold time and the appropriate data placed on the I/$\overline{O}$. When the MM5270A goes into write, the output circuit is disabled. If the TSP is low at the start of the cycle, the memory is not selected, but it will be refreshed if the chip enable clock is pulsed.



The RAM must be refreshed every 2 ms. This can be accomplished by performing a cycle at each of the 64 row addresses (A0–A5).

Addresses (A6–A11) must have a stable address during the refresh cycle. Any address is satisfactory as long as the address set-up and hold times are met. The chip select input can be either high or low for refresh.

features

- 4096 x 1 bit organization
- Access time–150 ns max
- Cycle time–300 ns min
- TRI-SHARE port
- High memory density–18-pin package
- TTL compatible inputs (except chip enable)
- TRI-STATE® common input/output
- Registers on chip for addresses and chip select
- Two power supplies, +12V, −5V
- Simple read-modify-write operation

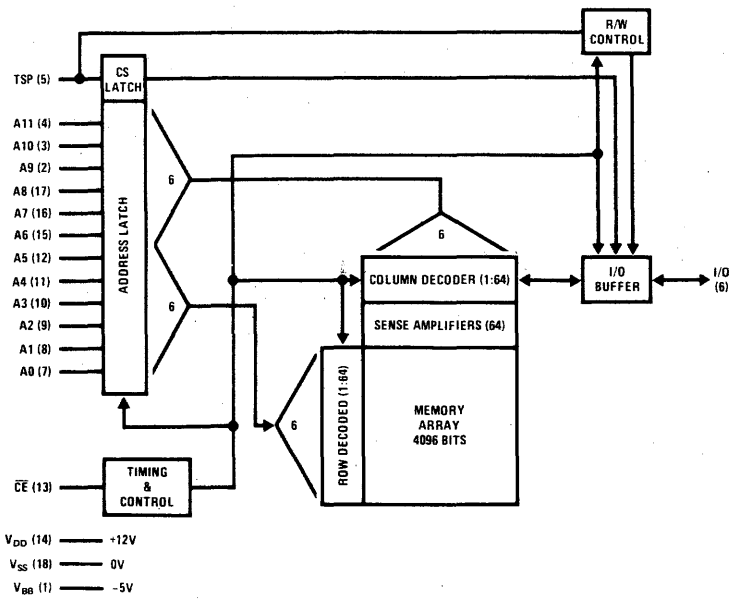
Advance Information

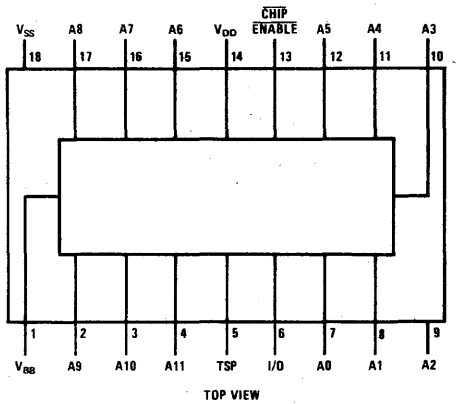
MM5271 TRI-SHARE™ 4096-bit fully TTL compatible dynamic random access read/write memory

general description



The MM5271 is a fully TTL compatible 4096-bit dynamic random access memory with TRI-SHARE. Because of this unique design feature, National is able to house a 4k device in an 18-pin dual-in-line package. The device is manufactured using N-channel silicon gate technology with a single transistor cell which provides higher density on a monolithic chip and thus lower cost.

The TRI-SHARE Port (TSP) is a multifunction input that, along with a common input/output, allows National to manufacture an 18-pin version of a 4k RAM. The functions controlled by the TSP are read/write, V_{CC}, and logical chip select. In order to understand how the TSP works, consider the timing diagrams. The state of the TSP at the leading edge of the chip enable clock determines whether the device is selected. If it is at a TTL high level, the chip is selected and the device goes into a read mode after chip enable goes high. This high level also controls the V_{CC} function in that it enables a reference voltage for a TTL high output. The supply for the output buffer is V_{DD}, not the TRI-SHARE Port; thus, no special driver is required. In order to perform a write, the TSP must be pulsed low after the minimum hold time and the appropriate data placed on the I/O. When the MM5271 goes into write, the output circuit is disabled. If the TSP is low at the start of the cycle, the memory is not selected but it will be refreshed when the chip enable clock is pulsed.



features

- 4096 x 1 bit organization
- Access time 250 ns maximum
- Cycle time 400 ns minimum
- TRI-SHARE port
- High memory density—18-pin package
- TTL compatible inputs
- TRI-STATE® common input/output
- Registers on chip for addresses and chip select
- Two power supplies, +12V, −5V
- Simple read-modify-write operation

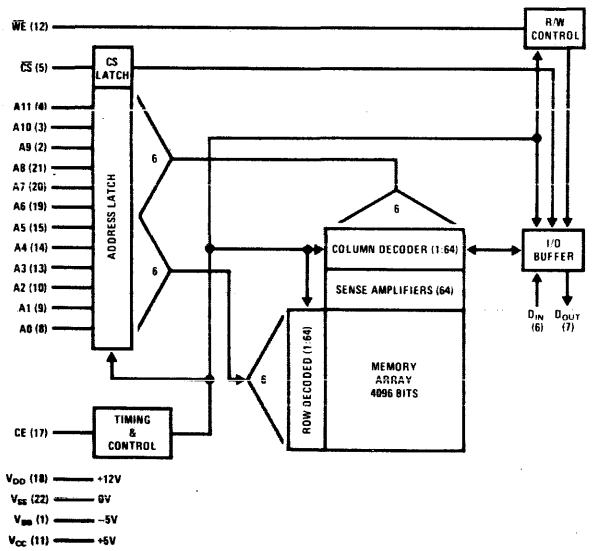
MOS RAMs

MM5280 4096-bit dynamic random access memory

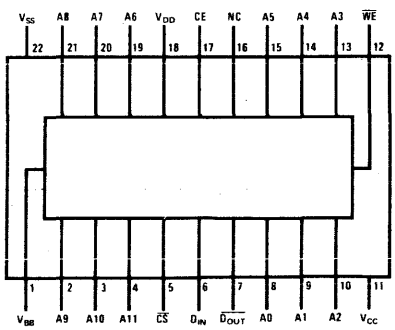
general description

National's MM5280 is a 4096 word by 1 bit dynamic RAM. It incorporates the latest memory design features and can be used in a wide variety of applications, from those which require very high speed to ones where low cost and large bit capacity are the prime criteria.



The MM5280 must be refreshed every 2 ms. This can be accomplished by performing a read cycle at each of the 64 row addresses (A0–A5). The chip select input can be either high or low for refresh.

The MM5280 has been designed with minimum production costs as a prime criterion. It is fabricated using N-channel silicon gate MOS technology, which is an ideal choice for high density integrated circuits. The MM5280 uses a single transistor cell to minimize the device area. The single device cell, along with unique design features in the on-chip peripheral circuits, yields a high performance memory device.



features

- Organization: 4096 x 1
- Access time 200 ns maximum
- Cycle time 400 ns minimum
- Easy system interface
  - One high voltage input—chip enable
  - TTL compatible—all other inputs and output
- Address registers on-chip
- TRI-STATE® output
- Simple read-modify-write operation
- Industry standard pin configuration

V_{IH}	Input High Voltage		2.4		V_{CC}+1	V
V_{ILC}	CE Input Low Voltage		−1.0		1.0	V
V_{IHC}	CE Input High Voltage		V_{DD}−1		V_{DD}+1	V
V_{OL}	Output Low Voltage	I_{OL} = 2.0 mA	0.0		0.45	V
V_{OH}	Output High Voltage	I_{OH} = −2.0 mA	2.4		V_{CC}	V

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: The only requirement for the sequence of applying voltage to the device is that V_{DD}, V_{CC}, and V_{SS} should never be 0.3V more negative than V_{BB}.

Note 3: Typical values are for T_A = 25°C and nominal power supply voltages.

Note 4: The I_{DD} and I_{CC} currents flow to V_{SS}. The I_{BB} current is the sum of all leakage currents.

Note 5: During CE "ON" V_{CC} supply current is dependent on output loading, V_{CC} is connected to output buffer only.

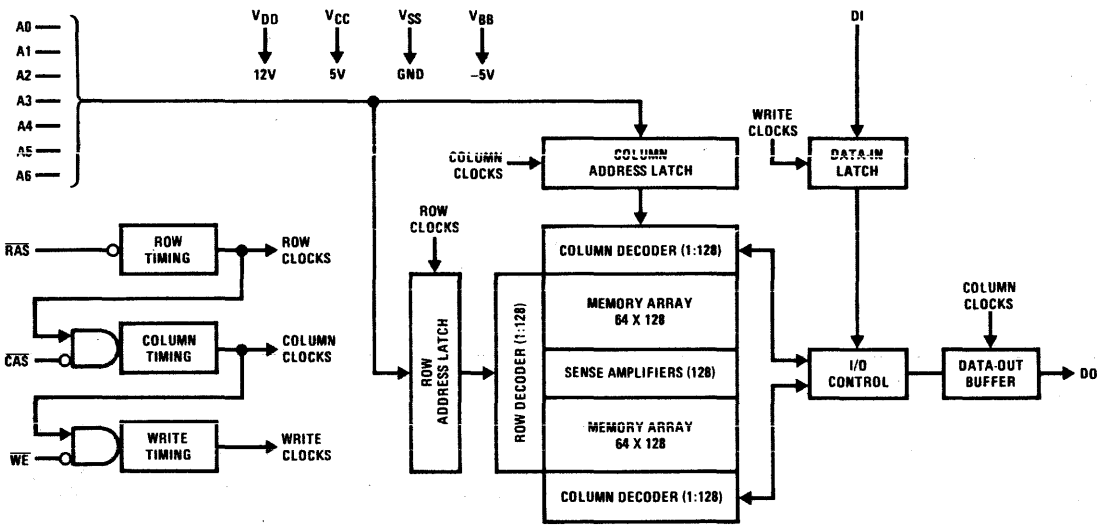
National Semiconductor

MM5290 16,384 × 1 Bit Dynamic RAM

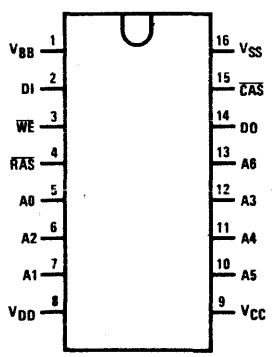
General Description

The MM5290 is a 16,384 x 1 bit dynamic RAM. It features a multiplexed address input with separate row and column strobes. This added flexibility allows the MM5290 to be used in page mode operation.



The MM5290 must be refreshed every 2 ms. This can be accomplished by performing any cycle which brings the Row Address Strobe active including a $\overline{RAS}$-only cycle at each of the 128 row addresses.

N-channel double-poly silicon gate technology, developed by National, is used in the manufacture of the MM5290. This process combines high density and performance with reliability. Greater system densities are achievable by the use of a 16-pin dual-in-line package for the MM5290.



Features

- Access times: 150 ns, 200 ns, 300 ns
- Low power: 462 mW max
- TTL compatible: all inputs and output
- Gated $\overline{CAS}$—noncritical timing
- Read, Write, Read-Modify-Write and $\overline{RAS}$-only Refresh cycles
- Page mode operation
- Industry standard 16-pin configuration

t_{CWD}	$\overline{CAS}$ to $\overline{WE}$ Delay	70		95		150		ns	15
t_{RWD}	$\overline{RAS}$ to $\overline{WE}$ Delay	120		160		250		ns	15

Note 7: The specifications for $t_{RC(MIN)}$ and $t_{RWC(MIN)}$ are used only to indicate cycle time at which proper operation over the full temperature range is guaranteed.

Note 8: Transition times are measured between V_{IHC} or V_{IH} and V_{IL}. Timing measurements are made between $V_{IHC(MIN)}$ or $V_{IH(MIN)}$ and $V_{IL(MAX)}$, and assume t_T = 5 ns.

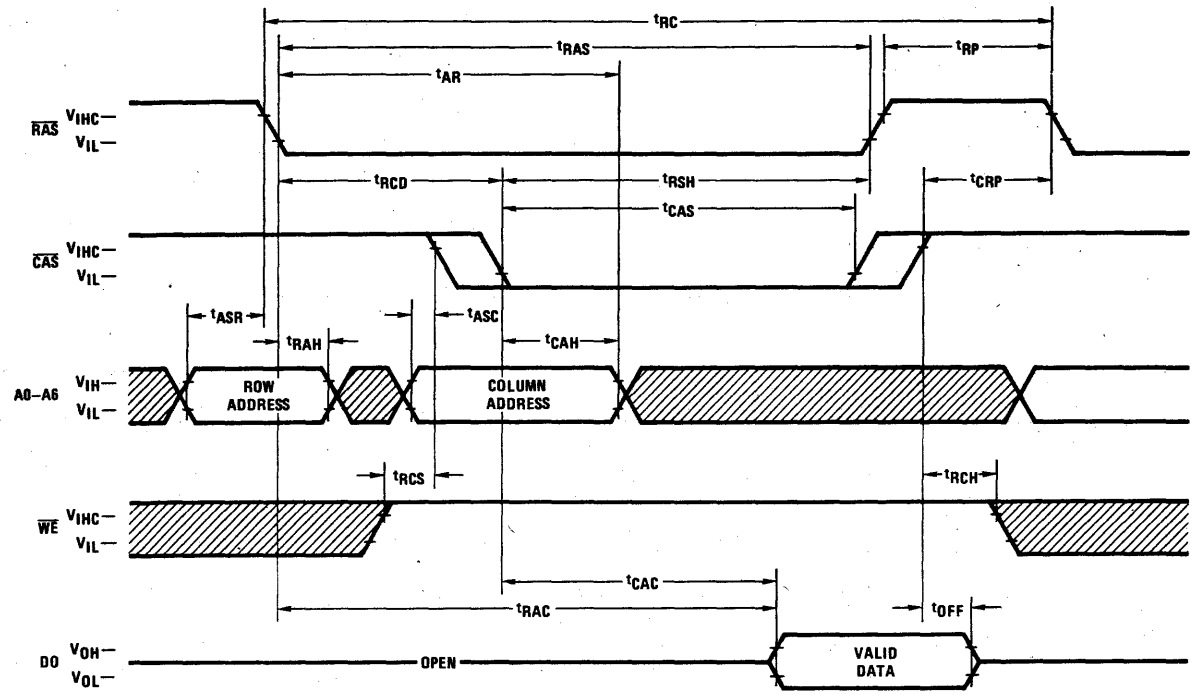
Note 9: Assumes row-limited access, i.e., $t_{RCD} \leq t_{RCD(MAX)}$. If this condition is not satisfied, then note 10 applies.

Note 10: Assumes column-limited access, i.e., $t_{RCD} > t_{RCD(MAX)}$.

Note 11: Equivalent load is 2 standard TTL inputs plus 100 pF.

Note 12: $\overline{CAS}$ going high disables the Data Output. t_{OFF} is the delay to the high impedance state.

Note 13: These parameters are referenced to the negative edge of $\overline{CAS}$ in an early-write cycle and to the negative edge of $\overline{WE}$ in a Read-Modify-Write cycle. (See Note 12, below).



Note 14: If $t_{WCS} \geq t_{WCS(MIN)}$, the Data Output is guaranteed to remain in the high impedance state for the duration of the cycle. This is the "early-write" cycle.

Note 15: If $t_{CWD} \geq t_{CWD(MIN)}$ and $t_{RWD} \geq t_{RWD(MIN)}$, the Data Output will contain the original data in the selected cell. This is the Read-Modify-Write cycle. If either of these conditions is not satisfied, the output will be indeterminate unless the early-write condition of Note 12 is met.

MM54C89/MM74C89 64-bit TRI-STATE® random access read/write memory

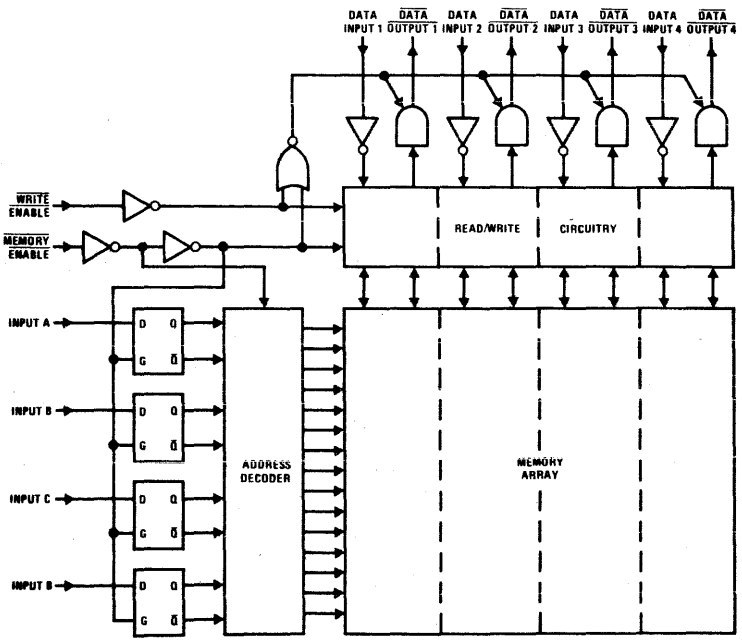
general description

The MM54C89/MM74C89 is a 16-word by 4-bit random access read/write memory. Inputs to the memory consist of four address lines, four data input lines, a write enable line and a memory enable line. The four binary address inputs are decoded internally to select each of the 16 possible word locations. An internal address register, latches the address information on the positive to negative transition of the memory enable input. The four TRI-STATE® data output lines working in conjunction with the memory enable input provides for easy memory expansion.

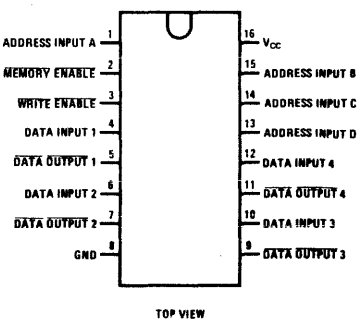
Address Operation: Address inputs must be stable t_{SA} prior to the positive to negative transition of memory enable. It is thus not necessary to hold address information stable for more than t_{HA} after the memory is enabled (positive to negative transition of memory enable).

Note: The timing is different than the DM7489 in that a positive to negative transition of the memory enable must occur for the memory to be selected.

Write Operation: Information present at the data inputs is written into the memory at the selected address by bringing write enable and memory enable low.



Read Operation: The complement of the information which was written into the memory is non-destructively read out at the four outputs. This is accomplished by selecting the desired address and bringing memory enable low and write enable high.



When the device is writing or disabled the output assumes a TRI-STATE (Hi-z) condition.

features

- Wide supply voltage range — 3.0V to 15V
- Guaranteed noise margin — 1.0V
- High noise immunity — 0.45 V_{CC} typ
- Low power TTL compatibility — fan out of 2 driving 74L
- Input address register
- Low power consumption — 100 nW/package typ @ V_{CC} = 5V
- Fast access time — 130 ns typ at V_{CC} = 10V
- TRI-STATE output

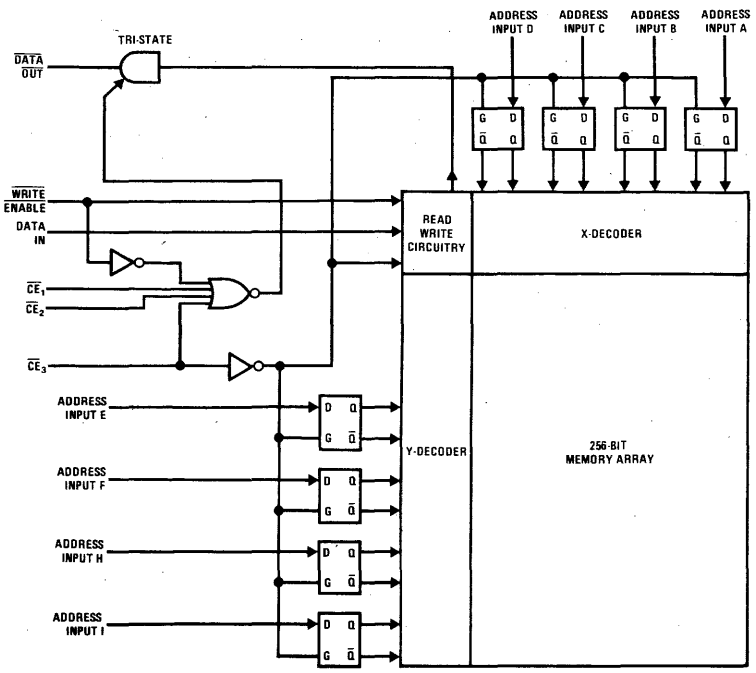
MM54C200/MM74C200 256-bit TRI-STATE® random access read/write memory

general description

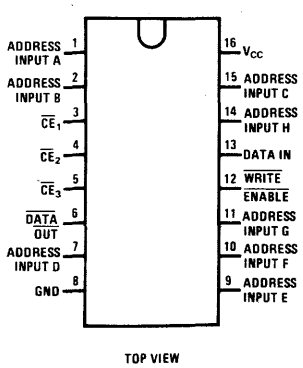
The MM54C200/MM74C200 is a 256-bit random access read/write memory. Inputs consist of eight address lines, a data input line, a write enable line, and three chip enables. The eight binary address inputs are decoded internally to select each of the 256 locations. An internal address register, latches and address information on the positive to negative edge of $\overline{CE}_3$. The TRI-STATE data output line working in conjunction with $\overline{CE}_1$ or $\overline{CE}_2$ inputs provides for easy memory expansion.

Address Operation: Address inputs must be stable t_{SA} prior to the positive to negative transition of $\overline{CE}_3$. It is thus not necessary to hold address information stable for more than t_{HA} after the memory is enabled (positive to negative transition).

Note: The timing is different than the DM74200 in that a positive to negative transition of the memory enable must occur for the memory to be selected.



Read Operation: The data is read out by selecting the proper address and bringing $\overline{CE}_3$ low and write enable high. Holding $\overline{CE}_1$ or $\overline{CE}_2$ or $\overline{CE}_3$ at a high level forces the output into TRI-STATE. When used in bus organized systems, $\overline{CE}_1$, or $\overline{CE}_2$, a TRI-STATE control, provides for fast access times by not totally disabling the chip.



Write Operation: Data is written into the memory with $\overline{CE}_3$ low and write enable low. The state of $\overline{CE}_1$ or $\overline{CE}_2$ has no effect on the write cycle. The output assumes TRI-STATE with write enable low.

features

■ Wide supply voltage range	3.0V to 15V
■ Guaranteed noise margin	1.0V
■ High noise immunity	0.45 V_{CC} typ
■ TTL compatibility	fan out of 1 driving standard TTL
■ Low power	500 nW typ
■ Internal address register

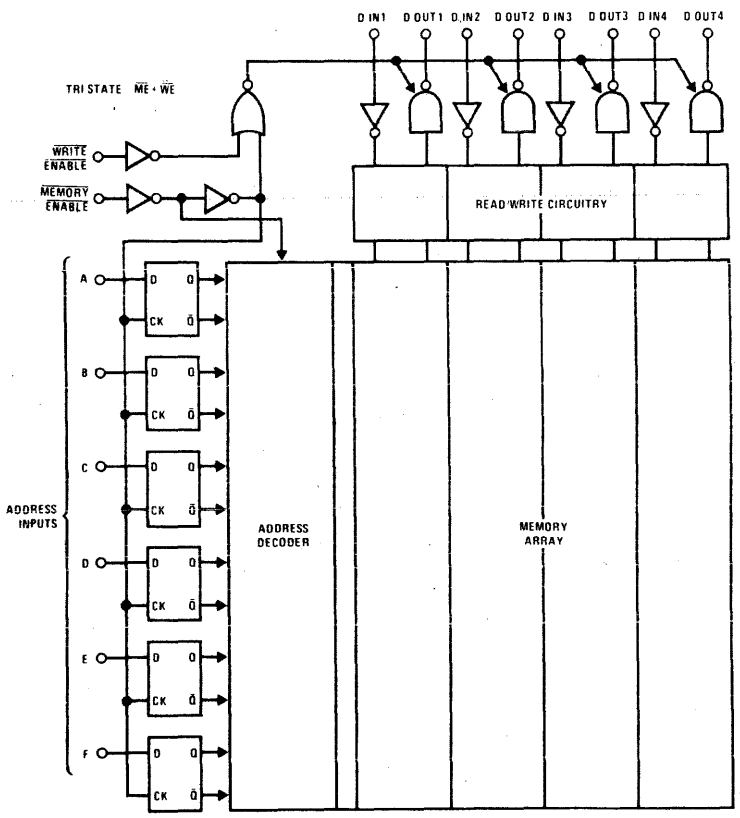
MM54C910/MM74C910 256-bit TRI-STATE® random access read/write memory

general description

The MM54C910/MM74C910 is a 64 word by 4 bit random access memory. Inputs consist of six address lines, four data input lines, a write enable, and a memory enable line. The six address lines are internally decoded to select one of 64 word locations. An internal address register, latches the address information on the positive to negative transition of memory enable. The TRI-STATE outputs allow for easy memory expansion.

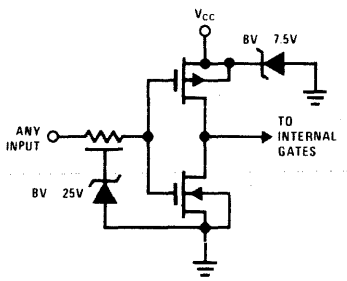
Address Operation: Address inputs must be stable (t_{SA}) prior to the positive to negative transition of memory enable, and (t_{HA}) after the positive to negative transition of memory enable. The address register holds the information and stable address inputs are not needed at any other time.

Write Operation: Data is written into memory at the selected address if write enable goes low while memory enable is low. Write enable must be held low for t_{WE} and data must remain stable t_{HD} after write enable returns high.



Read Operation: Data is nondestructively read from a memory location by an address operation with write enable held high.

Outputs are in the TRI-STATE (Hi-Z) condition when the device is writing or disabled.



features

- Supply voltage range — 3V to 5.5V
- High noise immunity — 0.45 V_{CC} typ
- TTL compatible fan out — 1 TTL load
- Input address register
- Low power consumption — 250 nW/package typ (chip enabled or disabled)
- Fast access time — 250 ns typ at 5V
- TRI-STATE outputs
- High voltage inputs

MM54C920/MM74C920, MM54C921/MM74C921
1024-bit static silicon gate CMOS RAMs

general description

The MM54C920/MM74C920 256 x 4 random access read/write memory is manufactured using silicon gate CMOS technology. Data output is the same polarity as data input. Internal latches store address inputs, $\overline{CES}$ and data output. This RAM is specifically designed to operate from standard 54/74 TTL power supplies. All inputs and outputs are TTL compatible.

The MM54C921/MM74C921 is identical to the MM54C920/MM74C920, except data inputs are internally connected to data outputs; the number of package leads thereby is reduced to 18.

Complete address decoding as well as two chip select functions, $\overline{CEL}$ and $\overline{CES}$, and TRI-STATE® outputs allow easy expansion with a minimum of external components. Versatility plus high speed and low power make these RAMs ideal elements for use in microprocessor, minicomputer as well as main frame memory applications.

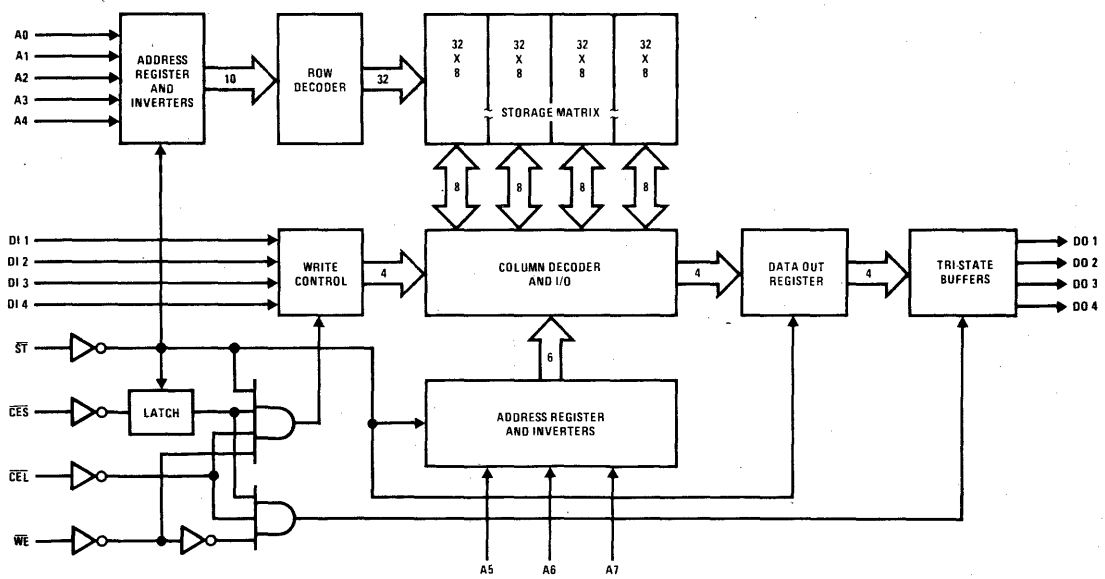
features

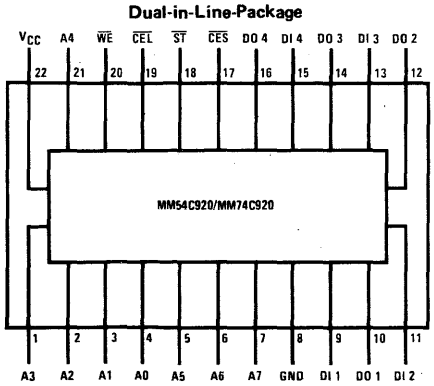
- Fast access—250 ns max
- TRI-STATE outputs
- Low power
- On-chip registers
- Single +5V supply
- Data retained with V_{CC} as low as 2V

functional description

The functional description will reference the logic diagram of the MM54C920/MM74C920 shown in *Figure 1.* Input addresses and $\overline{CES}$ are clocked into the input latches by the falling edge of $\overline{STROBE}$. Input setup and hold times must be observed on these signals (see timing diagrams). The true and complement address information is fed to the row and column decoders which access the selected 4-bit memory word.

logic and connection diagrams





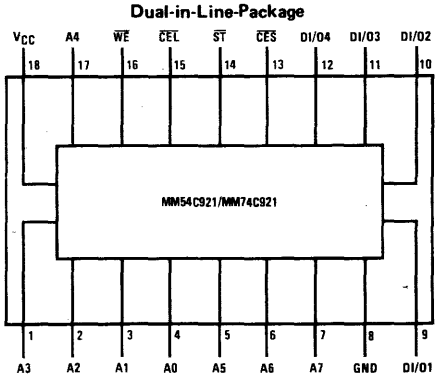


FIGURE 1. MM54C920/MM74C920 Logic Diagram

Dual-in-Line-Package

Dual-in-Line-Package

©IC MASTER 1978

functional description (con't)

The addressed word (4 bits) is fed to four sense amplifiers through the column decoders. The information from the sense amplifiers is retained in the output register when $\overline{STROBE}$ rises. The register drives the TRI-STATE output buffers.

Chip select inputs, $\overline{CEL}$ and $\overline{CES}$, have identical functions except that $\overline{CES}$ (Chip Enable Stored) is clocked into a latch on the falling edge of $\overline{STROBE}$; $\overline{CEL}$ (Chip Enable Level) is not.

Note that setup and hold times must be observed on $\overline{CES}$. Because $\overline{CEL}$ is not clocked by $\overline{STROBE}$, it may fall after $\overline{STROBE}$ has fallen without affecting access time.

The outputs are in a high impedance state when the chip is not selected ($\overline{CES}$ or $\overline{CEL}$ high) or when writing ($\overline{WE}$ low). Note that the information stored in the output latches will be changed whenever $\overline{STROBE}$ falls, regardless of the logic states of $\overline{WE}$, $\overline{CEL}$ or $\overline{CES}$.

The timing diagrams in *Figures 2, 3, and 4* define the read, write, and output enable/disable parameters respectively.

MM54C929/MM74C929, MM54C930/MM74C930
1024-bit static silicon gate CMOS RAMs

general description

The MM54C929/MM74C929 and the MM54C930/MM74C930 1024 x 1 random access read/write memories are manufactured using silicon gate CMOS technology. These RAMS are specifically designed to operate from standard 54/74 TTL power supplies; all inputs and outputs are TTL compatible. Data output is the same polarity as data input. Internal latches store the address inputs and data output. Chip select input $\overline{CS1}$ serves as a chip strobe, controlling address and data latching. The Data-In and Data-Out terminals can be tied together for common I/O applications. Complete address decoding, three chip select functions (MM54C930/MM74C930) and TRI-STATE® output allow easy memory expansion and organization. The MM54C929/MM74C929 differs from the MM54C930/MM74C930 only in that $\overline{CS1}$, $\overline{CS2}$ and $\overline{CS3}$ are internally connected together, providing a single chip-select input.

Versatility, high speed, and low power make these RAMs ideal elements for use in many microprocessor minicomputer and main frame memory applications.

features

- Fast access—250 ns max
- TRI-STATE outputs
- Low power—10μA max standby
- On-chip registers
- Single 5V supply
- Inputs and output TTL compatible
- Data retained with V_{CC} as low as 2V
- Can be operated common I/O

MOS EPROMs

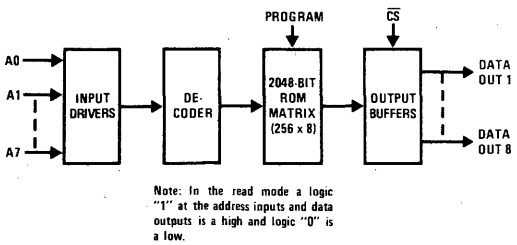
MM1702A 2048-bit electrically programmable ROM

general description

The MM1702A is a 256 word by 8-bit electrically programmable ROM ideally suited for uses where fast turn-around and pattern experimentation are important. The MM1702A undergoes complete programming and functional testing on each bit position prior to shipment, thus insuring 100% programmability.

The MM1702AQ is packaged in a 24-pin dual-in-line package with a transparent lid. The transparent lid allows the user to expose the chip to ultraviolet light to erase the bit pattern. A new pattern can then be written into the device. The MM1702AD is packaged in a 24-pin dual-in-line package with a metal lid and is not erasable.

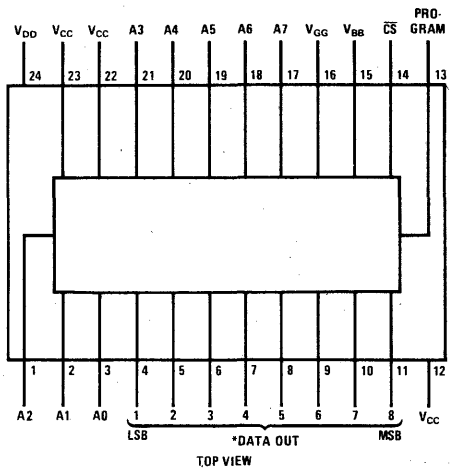
The circuitry of the MM1702A is entirely static; no clocks are required.



A pin-for-pin metal mask programmed ROM, the MM1302 is ideal for large volume production runs of systems initially using the MM1702A.

The MM1702A is fabricated with silicon gate technology. This low threshold technology allows the design and production of higher performance MOS circuits and provides a higher functional density on a monolithic chip than conventional MOS technologies.

features



- Fast programming—30 seconds for all 2048 bits
- All 2048 bits guaranteed programmable—100% factory tested
- Fully decoded, 256 x 8 organization
- Static MOS—no clocks required
- Inputs and outputs DTL and TTL compatible
- TRI-STATE® output—OR-tie capability
- Simple memory expansion—chip select input lead
- Direct replacement for the Intel 1702A

block and connection diagrams

Note: In the read mode a logic "1" at the address inputs and data outputs is a high and logic "0" is a low.

Dual-In-Line Package

*This pin is the data input lead during programming.

I_{OL}	Output Sink Current	V_{OUT} = 0.45V	1.6	4		mA
I_{OH}	Output Source Current	V_{OUT} = 0.0V	−2.0			mA
V_{OL}	Output Low Voltage	I_{OL} = 1.6 mA		−0.7	0.45	V
V_{OH}	Output High Voltage	I_{OH} = −100μA	3.5	4.5		V

Note 1: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and and functional operation of the device at these or at any other condition above those indicated in the operational sections of this specification is not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability.

Note 2: Power-Down Option: V_{GG} may be clocked to reduce power dissipation. The average I_{DD} will vary between I_{DD0} and I_{DD1} depending on the V_{GG} duty cycle (see typical characteristics). For this option, please specify MM1702AL.

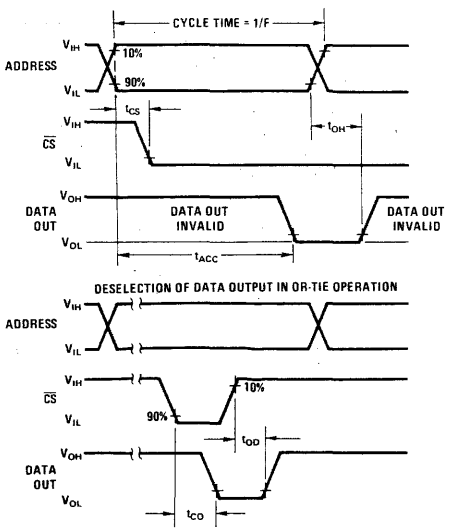
read operation ac characteristics

T_A = 0°C to +70°C, V_{CC} = +5V ±5%, V_{DD} = −9V ±5%, V_{GG} = −9V ±5%, unless otherwise noted.

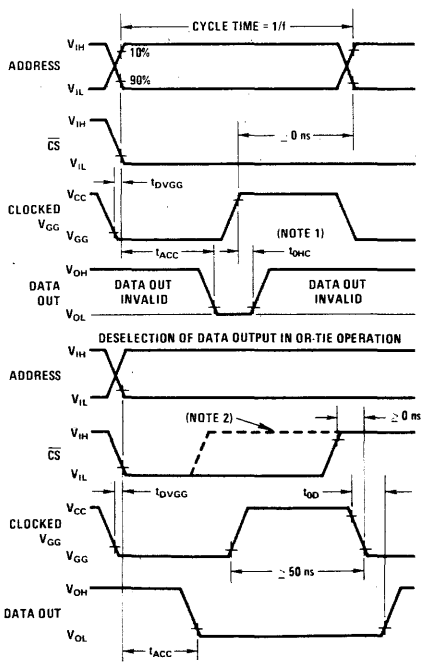
PARAMETER		MIN	TYP	MAX	UNITS
Freq.	Repetition Rate			1	MHz
t_{0H}	Previous Read Data Valid			100	ns
t_{ACC}	Address to Output Delay		0.7	1	μs
t_{DVGG}	Clocked V_{GG} Set-Up (Note 1)	1			μs
t_{CS}	Chip Select Delay			100	ns
t_{CO}	Output Delay From $\overline{CS}$			900	ns
t_{0D}	Output Deselect			300	ns
t_{0HC}	Data Out Hold in Clocked V_{GG} Mode (Note 1)			5	μs



capacitance characteristics T_A = 25°C (Note 3)

PARAMETER		CONDITIONS		MIN	TYP	MAX	UNITS
C_{IN}	Input Capacitance	All Unused	$V_{IN} = V_{CC}$		8	15	pF
C_{OUT}	Output Capacitance	Pins Are	$\overline{CS} = V_{CC}$		10	15	pF
C_{VGG}	V_{GG} Capacitance (Note 1)	At ac Ground	$V_{OUT} = V_{CC}$ $V_{GG} = V_{CC}$			30	pF

Note 3: This parameter is periodically sampled and is not 100% tested.



read operation switching time waveforms

(a) Constant V_{GG} Operation

Conditions of Test:
Input pulse amplitudes: 0–4V, t_r, $t_f \leq$ 50 ns. Output load is 1 TTL gate; measurements made at output of TTL gate ($t_{PD} \leq$ 15 ns), C_L = 15 pF.

(b) Power-Down Option (Note 1)

Note 1: The output will remain valid for t_{0HC} as long as clocked V_{GG} is at V_{CC}. An address change may occur as soon as the output is sensed (clocked V_{GG} may still be at V_{CC}). Data becomes invalid for the old address when clocked V_{GG} is returned to V_{GG}.

Note 2: If $\overline{CS}$ makes a transition from V_{IL} to V_{IH} while clocked V_{GG} is at V_{GG}, then deselection of output occurs at t_{0D} as shown in static operation with constant V_{GG}.

©IC MASTER 1978

programming operation dc characteristics

$T_A = 25°C$, $V_{CC} = 0V$, $V_{BB} = 12V \pm 10\%$, $\overline{CS} = 0V$ unless otherwise noted.

PARAMETER		CONDITIONS	MIN	TYP	MAX	UNITS
I_{LI1P}	Address and Data Input Load Current	$V_{IN} = -48V$			10	mA
I_{LI2P}	Program and V_{GG} Load Current	$V_{IN} = -48V$			10	mA
I_{BB}	V_{BB} Supply Load Current	(Note 5)		10	100	mA
I_{DDP}	Peak I_{DD} Supply Load Current	$V_{DD} = V_{PROG} = -48V$ $V_{GG} = -35V$ (Note 4)		200	300	mA
V_{IHP}	Input High Voltage				0.3	V
V_{IL1P}	Pulsed Data Input Low Voltage		−46		−48	V
V_{IL2P}	Address Input Low Voltage		−40		−48	V
V_{IL3P}	Pulsed Input Low V_{DD} and Program Voltage		−46		−48	V
V_{IL4P}	Pulsed Input Low V_{GG} Voltage		−35		−40	V

Note 4: I_{DDP} flows only during V_{DD}, V_{GG} on time. I_{DDP} should not be allowed to exceed 300 mA for greater than 100μs. Average power supply current I_{DDP} is typically 40 mA at 20% duty cycle.

Note 5: The V_{BB} supply must be limited to 100 mA max current to prevent damage to the device.

programming operation ac characteristics

$T_A = 25°C$, $V_{CC} = 0V$, $V_{BB} = 12V \pm 10\%$, $\overline{CS} = 0V$ unless otherwise noted.

PARAMETER		CONDITIONS	MIN	TYP	MAX	UNITS
	Duty Cycle (V_{DD}, V_{GG})				20	%
$t_{\phi PW}$	Program Pulse Width	$V_{GG} = -35V$, $V_{DD} = V_{PROG} = -48V$			3	ms
t_{DW}	Data Set-Up Time		25			μs
t_{DH}	Data Hold Time		10			μs
t_{VW}	V_{DD}, V_{GG} Set-Up		100			μs
t_{VD}	V_{DD}, V_{GG} Hold		10		100	μs
t_{ACW}	Address Complement Set-Up	(Note 6)	25			μs
t_{ACH}	Address Complement Hold	(Note 6)	25			μs
t_{ATW}	Address True Set-Up		10			μs
t_{ATH}	Address True Hold		10			μs

Note 6: All 8 address bits must be in the complement state when pulsed V_{DD} and V_{GG} move to their negative levels. The addresses (0–255) must be programmed as shown in the timing diagram until data reads true, then over-programmed 4 times that amount. (Symbolized by x + 4x.)

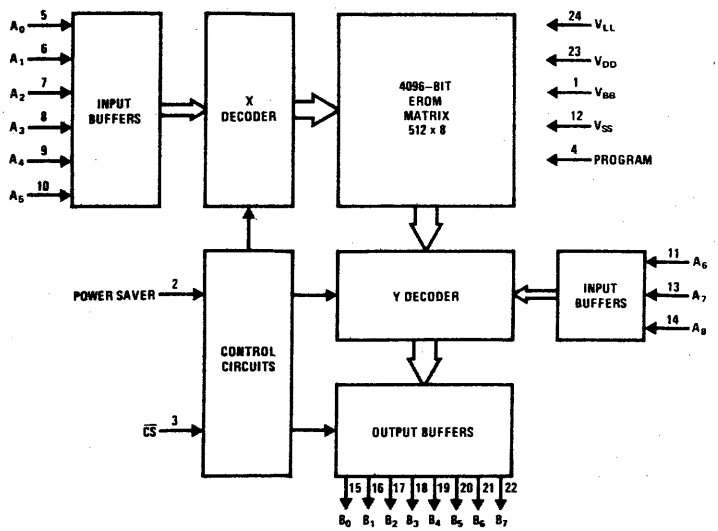
MOS EPROMs

MM4204/MM5204
electrically programmable 4096-bit read only memory (EROM)

general description

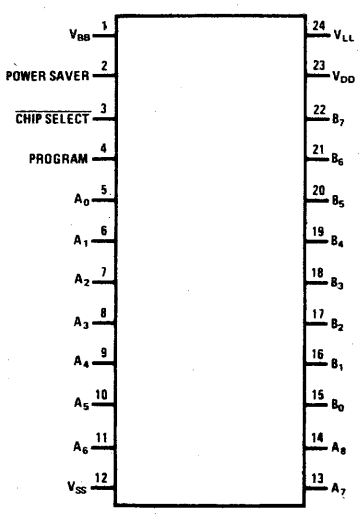
The MM4204/MM5204 is a 4096-bit static Read Only Memory which is electrically programmable and uses silicon gate technology to achieve bipolar compatiblity. The device is a non-volatile memory organized as 512 words by 8 bits per word. Programming of the memory is accomplished by storing a charge in a cell location by applying a −50V pulse. A logic input, "Power Saver," is provided which gives a 5:1 decrease in power when the memory is not being accessed.

- Standard power supplies 5.0V, −12V
- Static operation—no clock required
- Easy memory expansion—TRI-STATE® output Chip Select input ($\overline{CS}$)
- "Q" quartz lid version erasable with short wave ultraviolet light (i.e., 253.7 nm)
- Low power dissipation
- "Power Saver" control for low power applications



features

- Field programmable
- Fast program time: ten seconds typical for 4096-bits
- Fast access time
  - MM4204 1.25μs
  - MM5204 1μs
- DTL/TTL compatibility



applications

- Code conversion
- Random logic synthesis
- Table look-up
- Character generator
- Microprogramming
- Electronic keyboards

t_{PSH}	Power Saver Hold Time		1.0			μs
t_R, t_F	V_{DD}, Program, Address and Data Rise and Fall Time				1.0	μs

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: Capacitance is guaranteed by periodic testing.

Note 3: Positive true logic notation is used except on data inputs during programming
Logic "1" = most positive voltage level
Logic "0" = most negative voltage level

Note 4: t_{ACC} = 1000 ns + 25 (N-1) where N is the number of devices wire—OR'd together.

Note 5: The program cycle should be repeated until the data reads true, then over-programmed 5 times that number of cycles. (Symbolized as X + 5X programming).

Note 6: The EROM is initially programmed with all "0's." A V_{IHP} on any data input B0—B7 will leave the stored "0's" undisturbed, and a V_{ILP} on any data input B0—B7 will write a logic "1" into that location.

Note 7: Typical values are for nominal voltages and $T_A = 25°C$, unless otherwise specified.

erase specification

The recommended dosage of ultraviolet light exposure is 6W sec/cm².

programming

The MM4204/MM5204 is normally shipped in the unprogrammed state. All 4096-bits are at logic "0" state. The table of electrical programming characteristics and *Figure 2* give the conditions for programming of the device. In the program mode the device effectively becomes a RAM with the 512 word locations selected by address inputs A0—A8. Data inputs are B0—B7 and write operation is controlled by pulsing the Program input. Since the EROM is initially shipped with all "0's," a V_{IHP} on any data input B0—B7 will leave the stored "0's" undisturbed and a V_{ILP} on any data input B0—B7 will write a logic "1" into that location.

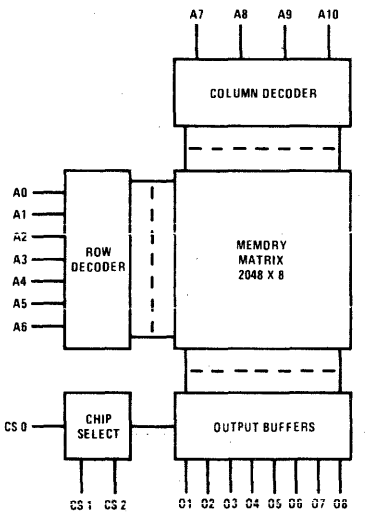
MM2316A 16,384-bit read only memory

general description

The MM2316A is a static MOS 16,384-bit read-only memory organized in a 2048-word-by-8-bit format. It is fabricated using N-channel enhancement and depletion-mode silicon-gate technology which provides complete DTL/TTL compatibility and single power-supply operation.

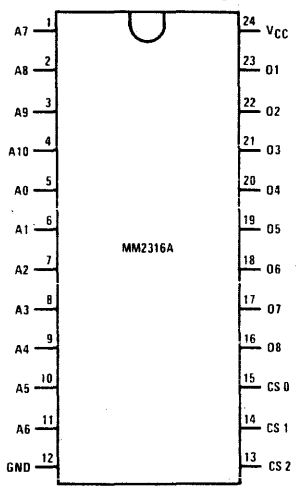
Three programmable chip selects controlling the TRI-STATE® outputs allow for memory expansion.

Programming of the memory array and chip-select active levels is accomplished by changing one mask during fabrication.



features

- Fully decoded
- Single 5V power supply
- Inputs and outputs TTL compatible
- Static operation
- TRI-STATE outputs for bus interface
- Programmable chip selects
- 2048 word by 8-bit organization
- Maximum access time—450 ns



applications

- Microprogramming
- Control logic
- Table look-up

PARAMETER (Note 3)	CONDITIONS	MIN	TYP (Note 4)	MAX	UNITS
t_{ACCESS}	See ac Load Circuit. All Times Measured to 1.5V Level with t_r and t_f of Input < 20 ns			450	ns
t_{SELECT}	See ac Load Circuit. All Times Measured to 1.5V Level with t_r and t_f of Input < 20 ns			300	ns
$t_{DESELECT}$	See ac Load Circuit. All Times Measured to 1.5V Level with t_r and t_f of Input < 20 ns			300	ns

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2: Capacitance is guaranteed by periodic testing.

Note 3: Positive true logic notation is used: logical "1" = most positive voltage level, logical "0" = most negative voltage level.

Note 4: Typical values are for T_A = 25°C and nominal supply voltage.

ELECTRONIC DISTRIBUTORS MASTER CATALOG

First published to serve you in 1935, The Radio Electronic Master has continuously changed over the years to better meet your needs. Today The Radio Master has become The Electronic Distributors MASTER CATALOG.

The 1978 edition of The Electronic Distributors MASTER CATALOG includes components, systems and subsystems sold through distributors.

It encompasses the following product areas: electronic and electromechanical components, audio and communications equipment, subassembly and panel components, hardware, production equipment and tools, test instrumentation, power sources, wire and cable, and chemicals.

The MASTER CATALOG is divided into four basic sections:

The **GENERAL INDEX** lists manufacturers and products alphabetically, including product cross references. Page numbers are displayed for both manufacturers and products. Manufacturers names are **bold-faced.**

The **MANUFACTURERS' CATALOG SECTION** is a collection of their respective product pages, alphabetically by manufacturer, again including addresses and phone numbers.

The **MANUFACTURERS DIRECTORY** is an alphabetical listing of all manufacturers whose products information is shown. Page numbers are referenced. Sales offices, representatives and distributors are included for many manufacturers.

The **DEALER/DISTRIBUTOR DIRECTORY** geographically lists distribution outlets by state and city. The listings were supplied by manufacturers cataloging in this edition.

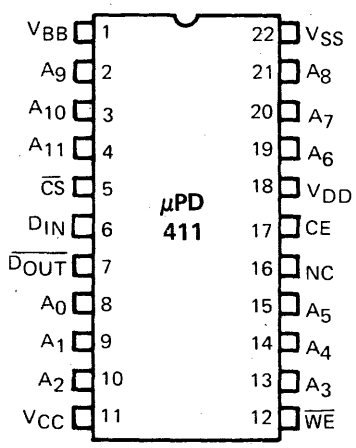
FULLY DECODED RANDOM ACCESS MEMORY

DESCRIPTION

The μPD411 Family consists of six 4096 words by 1 bit dynamic N-channel MOS RAMs. They are designed for memory applications where very low cost and large bit storage are important design objectives. The μPD411 Family is designed using dynamic circuitry which reduces the standby power dissipation.

Reading information from the memory is a non-destructive. Refreshing is easily accomplished by performing one read cycle on each of the 64 row addresses. Each row address must be refreshed every two milliseconds. The memory is refreshed whether Chip Select is a logic high or a logic low.

FEATURES



All of these products are guaranteed for operation over the 0 to 70°C temperature range.

Important features of the μPD411 family are:

- Low Standby Power
- 4096 words x 1 bit Organization
- A single low-capacitance high level clock input with solid ±1 volt margins.
- Inactive Power/0.3 mW (Typ.)
- Power Supply: +12, +5, -5V
- Easy System Interface
- TTL Compatible (Except CE)
- Address Registers on the Chip
- Simple Memory Expansion by Chip Select
- Three State Output and TTL Compatible
- 22 pin Ceramic Dual-in-Line Package
- Replacement for INTEL'S 2107B, TI'S 4060 and Equivalent Devices.
- 4 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	REFRESH TIME
μPD411-E	350 ns	800 ns	960 ns	1 ms
μPD411	300 ns	470 ns	650 ns	2 ms
μPD411-1	250 ns	470 ns	640 ns	2 ms
μPD411-2	200 ns	400 ns	520 ns	2 ms
μPD411-3	150 ns	380 ns	470 ns	2 ms
μPD411-4	135 ns	320 ns	320 ns	2 ms

FUNCTIONAL DESCRIPTION

CE Chip Enable

A single external clock input is required. All read, write, refresh and read-modify-write operations take place when chip enable input is high. When the chip enable is low, the memory is in the low power standby mode. No read/write operations can take place because the chip is automatically precharging.

$\overline{CS}$ Chip Select

The chip select terminal affects the data in, data out and read/write inputs. The data input and data output terminals are enabled when chip select is low. The chip select input must be low on or before the rising edge of the chip enable and can be driven from standard TTL circuits. A register for the chip select input is provided on the chip to reduce overhead and simplify system design.

$\overline{WE}$ Write Enable

The read or write mode is selected through the write enable input. A logic high on the $\overline{WE}$ input selects the read mode and a logic low selects the write mode. The $\overline{WE}$ terminal can be driven from standard TTL circuits. The data input is disabled when the read mode is selected.

A_0–A_{11} Addresses

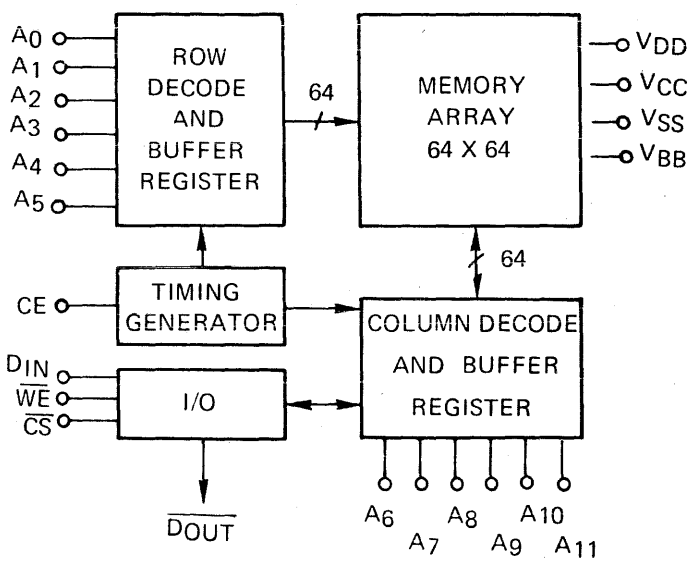
All addresses must be stable on or before the rising edge of the chip enable pulse. All address inputs can be driven from standard TTL circuits. Address registers are provided on the chip to reduce overhead and simplify system design.

D_{IN} Data Input

Data is written during a write or read-modify-write cycle while the chip enable is high. The data in terminal can be driven from standard TTL circuits. There is no register on the data in terminal.

$\overline{D_{OUT}}$ Data Output

The three state output buffer provides direct TTL compatibility with a fan-out of two TTL gates. The output is in the high-impedance (floating) state when the chip enable is low or when the Chip Select input is high. Data output is inverted from data in.



Refresh

Refresh must be performed every two milliseconds by cycling through the 64 addresses of the lower-order-address inputs A_0 through A_5 or by addressing every row within any 2*-millisecond period. Addressing any row refreshes all 64 bits in that row.

The chip does not need to be selected during the refresh. If the chip is refreshed during a write mode, the chip select must be high.

*μPD411-E = 1 millisecond refresh period.

FUNCTIONAL DESCRIPTION

CE Chip Enable

A single external clock input is required. All read, write, refresh and read-modify-write operations take place when chip enable input is high. When the chip enable is low, the memory is in the low power standby mode. No read/write operations can take place because the chip is automatically precharging.

$\overline{CS}$ Chip Select

The chip select terminal affects the data in, data out and read/write inputs. The data input and data output terminals are enabled when chip select is low. The chip select input must be low on or before the rising edge of the chip enable and can be driven from standard TTL circuits. A register for the chip select input is provided on the chip to reduce overhead and simplify system design.

$\overline{WE}$ Write Enable

The read or write mode is selected through the write enable input. A logic high on the $\overline{WE}$ input selects the read mode and a logic low selects the write mode. The $\overline{WE}$ terminal can be driven from standard TTL circuits. The data input is disabled when the read mode is selected.

A_0–A_{11} Addresses

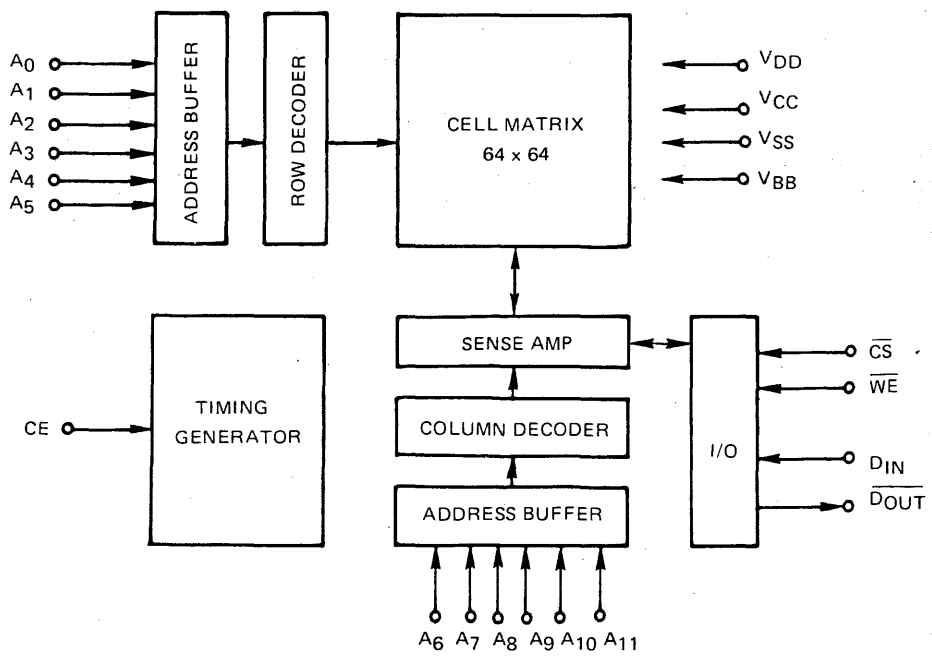
All addresses must be stable on or before the rising edge of the chip enable pulse. All address inputs can be driven from standard TTL circuits. Address registers are provided on the chip to reduce overhead and simplify system design.

D_{IN} Data Input

Data is written during a write or read-modify-write cycle while the chip enable is high. The data in terminal can be driven from standard TTL circuits. There is no register on the data in terminal.

$\overline{D_{OUT}}$ Data Output

The three state output buffer provides direct TTL compatibility with a fan-out of two TTL gates. The output is in the high-impedance (floating) state when the chip enable is low or when the Chip Select input is high. Data output is inverted from data in.



Refresh

Refresh must be performed every two milliseconds by cycling through the 64 addresses of the lower-order-address inputs A_0 through A_5 or by addressing every row within any 2*-millisecond period. Addressing any row refreshes all 64 bits in that row.

The chip does not need to be selected during the refresh. If the chip is refreshed during a write mode, the chip select must be high.

*μPD411A-E = 1 millisecond refresh period.

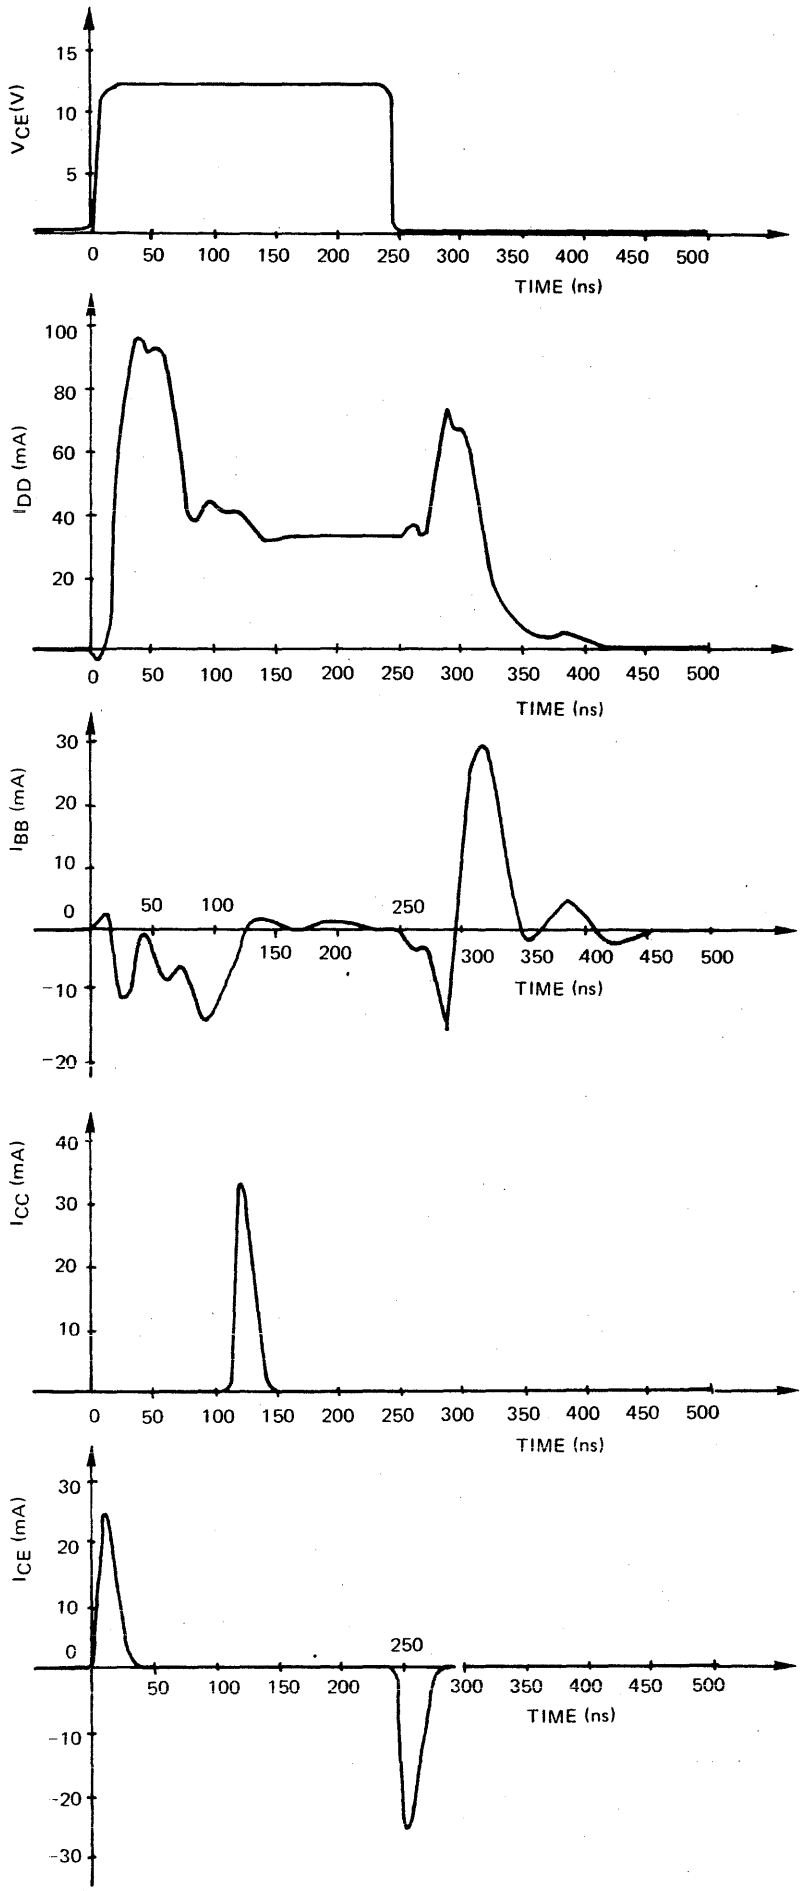
TYPICAL OPERATING CHARACTERISTICS

POWER CONSUMPTION

Power consumption = $V_{DD} \times I_{DDAV} + V_{BB} \times I_{BB}$



Typical power dissipation for each product is shown below.

	mW (TYP.)	CONDITIONS
μPD411A-E	300 mW	$T_a = 25°C$, $t_{cy} = 800$ ns, $t_{CE} = 380$ ns
μPD411A	460 mW	$T_a = 25°C$, $t_{cy} = 470$ ns, $t_{CE} = 300$ ns
μPD411A-1	460 mW	$T_a = 25°C$, $t_{cy} = 430$ ns, $t_{CE} = 260$ ns
μPD411A-2	460 mW	$T_a = 25°C$, $t_{cy} = 400$ ns, $t_{CE} = 230$ ns

See curve above for power dissipation versus cycle time.

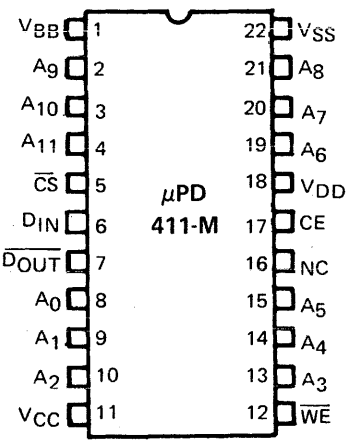
4096 BIT DYNAMIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The μPD411-M Family consists of three 4096 words by 1 bit dynamic N-channel MOS RAMs. They are designed for memory applications where wide operating environmental temperatures are important design considerations. The μPD411-M Family is designed using dynamic circuitry which reduces the standby power dissipation.



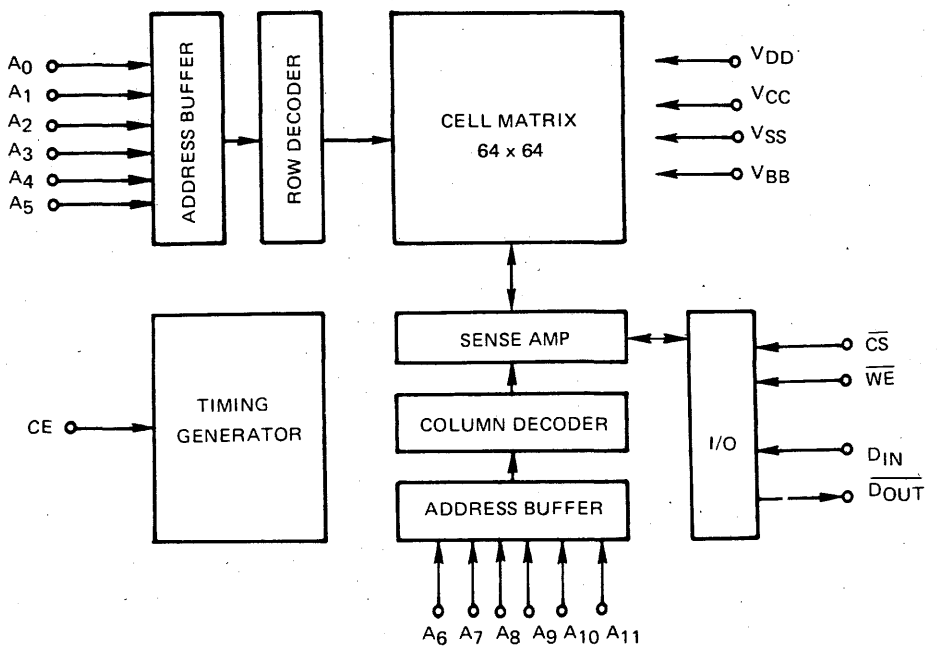
Reading information from the memory is non-destructive. Refreshing is easily accomplished by performing one read cycle on each of the 64 row addresses. Each row address must be refreshed every two milliseconds. The memory is refreshed whether Chip Select is a logic high or a logic low.*

FEATURES

- 4096 Words x 1 Bit Organization.
- Wide Operating Temperature Range (T_a = −40 to +85°C).
- TTL Compatibility on All Inputs (except CE).
- Three-State Output Providing TTL Compatibility.
- 22 Pin Dual-In-Line Ceramic Package.
- 3 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	REFRESH TIME	POWER DISSIPATION
μPD411-M	300 ns	470 ns	650 ns	2 ms	65 mA
μPD411-1M	250 ns	430 ns	600 ns	2 ms	65 mA
μPD411-2M	200 ns	400 ns	520 ns	2 ms	65 mA

PIN CONFIGURATION



PIN NAMES

$A_0 - A_{11}$	Address Inputs
$A_0 - A_5$	Refresh Addresses
CE	Chip Enable
$\overline{CS}$	Chip Select
D_{IN}	Data Input
$\overline{D_{OUT}}$	Data Output
$\overline{WE}$	Write Enable
V_{DD}	Power (+12V)
V_{CC}	Power (+5V)
V_{SS}	Ground
V_{BB}	Power (-5V)
NC	No Connection

Supply Voltage V_{SS}	−0.3 to +20 Volts ②
CE Input Voltage	−0.3 to +20 Volts
Power Dissipation	1.0W

Notes: ① Still Air
② Relative to V_{BB}

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C.

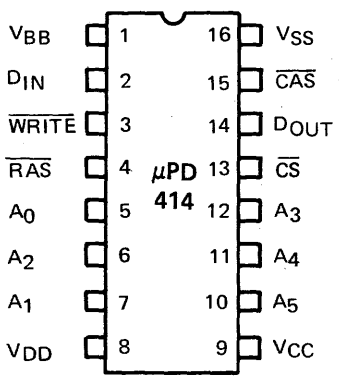
FULLY DECODED RANDOM ACCESS 4096 BIT DYNAMIC MEMORY

DESCRIPTION

The NEC μPD414 is a 4096 words by 1 bit Dynamic N channel MOS RAM. It was designed for memory applications where very low cost and large bit storage are important design objectives. The μPD414 uses a single transistor dynamic storage cell and dynamic circuitry to achieve high speed and low power dissipation.

The μPD414 is packaged in the standard 16 pin dual-in-line package. The 16 pin package provides the highest system bit densities and is available in either cerdip or plastic.

The use of the 16 pin package is made possible by multiplexing the 12 address bits (required to address 1 of 4096 bits) into the μPD414 on 6 address input pins. The two 6 bit address words are latched into the μPD414 by the two TTL clocks, Row Address Strobe ($\overline{RAS}$) and Column Address Strobe ($\overline{CAS}$). Noncritical clock timing requirements allow use of the multiplexing technique while maintaining high performance.



The single transistor dynamic storage cell provides high speed along with low power dissipation. The memory cell requires refreshing for data retention. Refreshing is most easily accomplished by performing a read cycle at each of the 64 row addresses every 2 milliseconds.

FEATURES

- 4096 Words x 1 Bit Organization
- Refresh Period 2 ms
- Standard 16 Pin Cerdip and Plastic Packages
- Low Standby Power
- All Inputs Including Clocks TTL Compatible
- Standard Power Supplies +12V, +5V, -5V
- Gated $\overline{CAS}$ Characteristic
- On-Chip Latches for Addresses, Chip Select and Data In
- Simple Memory Expansion Chip Select
- Output is Three State, TTL Compatible; Data is Latched and Valid into Next Cycle
- 4 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE
μPD414-E	350 ns	500 ns	700 ns
μPD414	300 ns	425 ns	590 ns
μPD414-1	250 ns	375 ns	480 ns
μPD414-2	200 ns	375 ns	420 ns

Average V_{DD} Current	$I_{DD}AV$ ③			35	mA	Cycle time = Min ④ t_{RP} = 150 ns, T_a = 25°C
V_{CC} Supply Current when deselected	$I_{CC}OFF$			10	μA	⑧
Average V_{BB} Current	I_{BB} ③			75	μA	
Average V_{DD} Power Supply Current During "$\overline{RAS}$ only" cycles	I_{DD3}			28	mA	④
Input Low Voltage (any input)	V_{IL}	−1.0		0.8	V	①⑨
Input High Voltage except $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IH}	2.4		7.0	V	①⑨
Output Low Voltage	V_{OL}	0		0.4	V	I_{OL} = 2.0 mA
Output High Voltage	V_{OH}	2.4		7.0	V	I_{OH} = −5.0 mA
Supply Voltage	V_{DD}	10.8	12.0	13.2	V	①
Supply Voltage	V_{CC}	V_{SS}	5.0	V_{DD}	V	① ⑩
Supply Voltage	V_{SS}	0	0	0	V	①
Supply Voltage	V_{BB}	−4.5	−5.0	−5.5	V	①
Logic 1 Voltage, $\overline{RAS}$, $\overline{CAS}$, $\overline{WRITE}$	V_{IHC}	2.7		7.0	V	⑨

Notes:
① All voltages referenced to V_{SS}. V_{BB} must be applied before and removed after other supply voltages.
② Typical values are for T_a = 25°C and nominal power supply voltages.
③ The I_{DD} current flows to V_{SS}. The I_{BB} current is the sum of all leakage currents.
④ Current is proportional to cycle rate; maximum current is measured at the fastest cycle rate.
⑤ All device pins at 0 volts except V_{BB} which is at −5 volts and the pin under test which is at +10 volts.
⑥ Output is disabled (open-circuit) and $\overline{RAS}$ and $\overline{CAS}$ are both at a logic 1.
⑦ $0V \leqslant V_{OUT} \leqslant +10V$.
⑧ When chip is selected V_{CC} supply current is dependent on output loading; V_{CC} is connected to output buffer only.
⑨ Device speed is not guaranteed at input voltages greater than TTL levels (0 to +5V).
⑩ Output voltage will swing from V_{SS} to V_{CC} if $V_{CC} \leqslant V_{DD}$ −4 volts. If $V_{CC} \geqslant V_{DD}$ −4 volts, the output will swing from V_{SS} to a voltage somewhat less than V_{DD}.

$\overline{CAS}$ to $\overline{WRITE}$ delay	t_{CWD}	200			165			90			80			ns	⑩
$\overline{RAS}$ to $\overline{WRITE}$ delay	t_{RWD}	350			300			175			145			ns	⑩

Notes:
① A.C. measurements assume t_T = 5 ns.
② Minimum cylce time (t_{RC}) is greater than $t_{RAS} + t_{RP} + 2t_T$ in order to limit power dissipation.
③ Assumes that $t_{RCL} + t_T \leq t_{RCL}$ (max).
④ Assumes that $t_{RCL} + t_T \geq t_{RCL}$ (max).
⑤ Measured with a load circuit equivalent to 2 TTL loads and 100 pF.
⑥ Assumes that $t_{RCL} + t_T \geq t_{RCL}$ (max). If $t_{RCL} + t_T < t_{RCL}$ (max), $60 + t_{RCL}$ (max) − $t_{RCL} - t_T$ ns min.
⑦ Operation within the t_{RCL} (max) limit insures that t_{RAC} (max) can be met. t_{RCL} (max) is specified as a reference point only; if t_{RCL} is greater than the specified t_{RCL} (max) limit, then access time is controlled exclusively by t_{CAC}.
⑧ V_{IHC} (min) or V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}.
⑨ These parameters are referenced to $\overline{CAS}$ leading edge in random write cycles and to $\overline{WRITE}$ leading edge in delayed write or read-modify-write cycles.
⑩ t_{CWD} and t_{RWD} are not restrictive operating parameters. They are included in the data sheet as electrical characteristics only:
If $t_{CWD} + t_T \leq t_{CWD}$ (min), the data out latch will contain high level data.
If $t_{CWD} \geq t_{CWD}$ (max) + t_T and $t_{RWD} \geq t_{RWD}$ (max) + t_T, the data out latch will contain the data read from the selected cell.
If t_{CWD} does not meet the above constraints, then data out latch will contain indeterminate data.

ADDRESSING

The 12 address bits required to decode 1 of 4096 bit locations are multiplexed onto the 6 address pins and then latched on the chip with the use of the Row Address Strobe ($\overline{RAS}$), and the Column Address Strobe ($\overline{CAS}$). The 6 bit row address is first applied and $\overline{RAS}$ is then brought low. After the $\overline{RAS}$ hold time has elapsed, the column address and chip select signals are applied and $\overline{CAS}$ is brought low. Since the column address and chip select are not needed internally until a time of t_{RCL} MAX after the row address, this multiplexing operation imposes no penalty on access time as long as $\overline{CAS}$ is applied no later than t_{RCL} MAX. If this time is exceeded, access time will be defined from $\overline{CAS}$ instead of $\overline{RAS}$.

DATA I/O

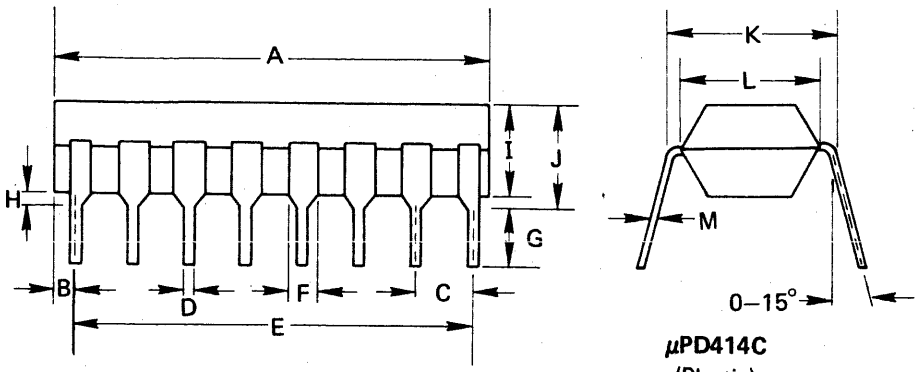
For a write operation, the input data is latched on the chip by the negative going edge of $\overline{WRITE}$ or $\overline{CAS}$, whichever occurs later. If $\overline{WRITE}$ is active before $\overline{CAS}$, Data out will unconditionally assume a logic "1" state. If $\overline{WRITE}$ is mode active after the access time, as in a read/write cycle, the output will reflect the data read. The output data is latched and will remain in its proper state until the next negative transition of $\overline{CAS}$.

PAGE MODE

The μPD414 may also be operated in page mode for either reading or writing by keeping $\overline{RAS}$ low after strobing in the row address, and cycling $\overline{CAS}$ for each new column address.

REFRESH

Refresh of the memory matrix is accomplished by performing a memory cycle at each of the 64 row addresses every 2 milliseconds or less. Any memory cycle will refresh the chip regardless of the state of chip select although the chip must be deselected if a write cycle is used to avoid altering data. The data output will go to the high impedance state if chip select is high when $\overline{CAS}$ is brought low.



Refresh may also be achieved by cycling $\overline{RAS}$ only and strobing in each of the 64 row addresses. The data output will remain unaffected by this "$\overline{RAS}$-only" refresh.

$\overline{CAS}$ ONLY OPERATION

If $\overline{RAS}$ is decoded and applied only to the desired chips, the remaining chips will dissipate no power on the $\overline{CAS}$ edges. In addition, the outputs will assume the high impedance state regardless of chip select.

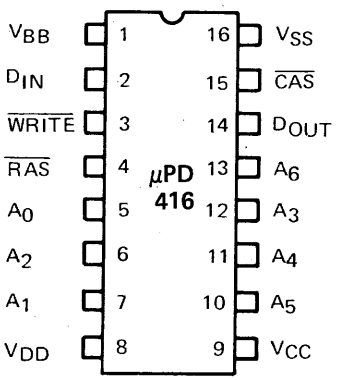
16384 x 1 BIT DYNAMIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The NEC μPD416 is a 16384 words by 1 bit Dynamic MOS RAM. It is designed for memory applications where very low cost and large bit storage are important design objectives.

The μPD416 is fabricated using a double-poly-layer N channel silicon gate process which affords high storage cell density and high performance. The use of dynamic circuitry throughout, including the sense amplifiers, assures minimal power dissipation.



Multiplexed address inputs permit the μPD416 to be packaged in the standard 16 pin dual-in-line package. The 16 pin package provides the highest system bit densities and is available in either ceramic or plastic. Noncritical clock timing requirements allow use of the multiplexing technique while maintaining high performance.

FEATURES

- 16384 Words x 1 Bit Organization
- High Memory Density – 16 Pin Ceramic and Plastic Packages
- Multiplexed Address Inputs
- Standard Power Supplies +12V, -5V, +5V
- Low Power Dissipation; 462 mW Active (MAX), 20 mW Standby (MAX)
- Output Data Controlled by $\overline{CAS}$ and Unlatched at End of Cycle
- Read-Modify-Write, $\overline{RAS}$-only Refresh, and Page Mode Capability
- All Inputs TTL Compatible, and Low Capacitance
- 128 Refresh Cycles
- 4 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE
μPD416	300 ns	510 ns	510 ns
μPD416-1	250 ns	430 ns	430 ns
μPD416-2	200 ns	375 ns	375 ns
μPD416-3	150 ns	375 ns	375 ns

Output High Voltage (Logic 1)	V_{OH}	2.4			V	I_{OUT} = -5 mA ③
Output Low Voltage (Logic 0)	V_{OL}			0.4	V	I_{OUT} = 4.2 mA

Notes: ① T_a is specified here for operation at frequencies to $t_{RC} \geq t_{RC}$ (min). Operation at higher cycle rates with reduced ambient temperatures and high power dissipation is permissible, however, provided AC operating parameters are met. See Figure 1 for derating curve.

② All voltages referenced to V_{SS}.

③ Output voltage will swing from V_{SS} to V_{CC} when activated with no current loading. For purposes of maintaining data in standby mode, V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention. However, the V_{OH} (min) specification is not guaranteed in this mode.

④ I_{DD1}, I_{DD3}, and I_{DD4} depend on cycle rate. See Figures 2, 3 and 4 for I_{DD} limits at other cycle rates.

⑤ I_{CC1} and I_{CC4} depend upon output loading. During readout of high level data V_{CC} is connected through a low impedance (135Ω typ) to data out. At all other times I_{CC} consists of leakage currents only.

RAS to $\overline{WRITE}$ delay	t_{RWD}	210		175		160		120		ns	

Notes:

① AC measurements assume t_T = 5 ns.

② V_{IHC} (min) or V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IHC} or V_{IH} and V_{IL}.

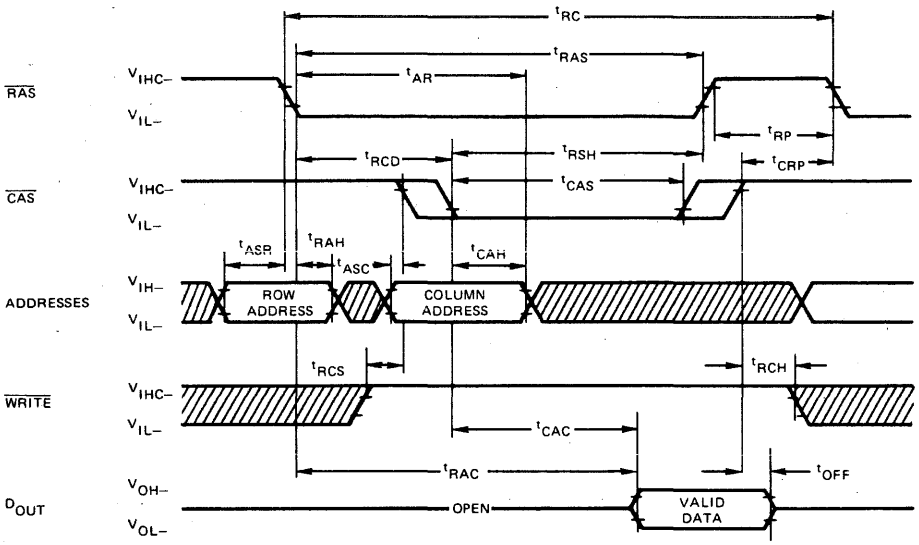
③ The specifications for t_{RC} (min) and t_{RWC} (min) are used only to indicate cycle time at which proper operation over the full temperature range (0°C ≤ T_a ≤ 70°C) is assured.

④ Assumes that $t_{RCD} \leq t_{RCD}$ (max). If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the values shown.

⑤ Assumes that $t_{RCD} \geq t_{RCD}$ (max).

⑥ Measured with a load equivalent to 2 TTL loads and 100 pF.

⑦ t_{OFF} (max) defines the time at which the output achieves the open circuit condition and is not referenced to output voltage levels.



⑧ Operation within the t_{RCD} (max) limit ensures that t_{RAC} (max) can be met. t_{RCD} (max) is specified as a reference point only, if t_{RCD} is greater than the specified t_{RCD} (max) limit, then access time is controlled exclusively by t_{CAC}.

⑨ These parameters are referenced to $\overline{CAS}$ leading edge in early write cycles and to $\overline{WRITE}$ leading edge in delayed write or read-modify-write cycles.

ADDRESSING

The 14 address bits required to decode 1 of 16,384 bit locations are multiplexed onto the 7 address pins and then latched on the chip with the use of the Row Address Strobe ($\overline{RAS}$), and the Column Address Strobe ($\overline{CAS}$). The 7 bit row address is first applied and $\overline{RAS}$ is then brought low. After the $\overline{RAS}$ hold time has elapsed, the 7 bit column address is applied and $\overline{CAS}$ is brought low. Since the column address is not needed internally until a time of t_{CRD} MAX after the row address, this multiplexing operation imposes no penalty on access time as long as $\overline{CAS}$ is applied no later than t_{CRD} MAX. If this time is exceeded, access time will be defined from $\overline{CAS}$ instead of $\overline{RAS}$.

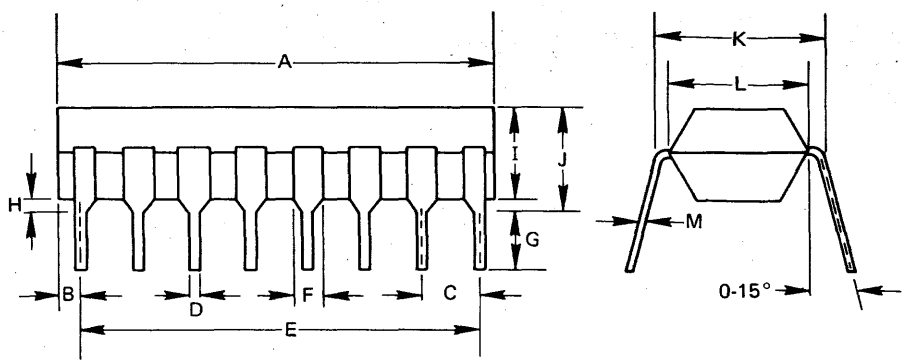
DATA I/O

For a write operation, the input data is latched on the chip by the negative going edge of $\overline{WRITE}$ or $\overline{CAS}$, whichever occurs later. If $\overline{WRITE}$ is active before $\overline{CAS}$, this is an "early WRITE" cycle and data out will remain in the high impedance state throughout the cycle. For a READ, WRITE, OR READ-MODIFY-WRITE cycle, the data output will contain the data in the selected cell after the access time. Data out will assume the high impedance state anytime that $\overline{CAS}$ goes high.

PAGE MODE

The page mode feature allows the μPD416 to be read or written at multiple column addresses for the same row address. This is accomplished by maintaining a low on $\overline{RAS}$ and strobing the new column addresses with $\overline{CAS}$. This eliminates the setup and hold times for the row address resulting in faster operation.

REFRESH



Refresh of the memory matrix is accomplished by performing a memory cycle at each of the 128 row addresses every 2 milliseconds or less. Because data out is not latched, "$\overline{RAS}$ only" cycles can be used for simple refreshing operation.

CHIP SELECTION

Either $\overline{RAS}$ and/or $\overline{CAS}$ can be decoded for chip select function. Unselected chip outputs will remain in the high impedance state.

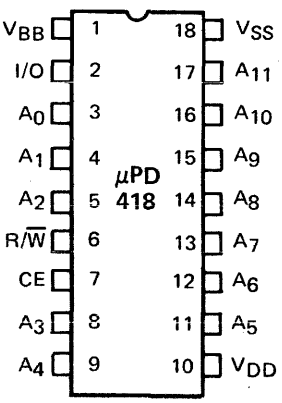
4096 BIT DYNAMIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The μPD418 series is composed of high speed, dynamic, 4096 words x 1 bit, N channel, MOS, random access memories.

All inputs, except the clock (chip enable), are fully TTL compatible and require no pull-up resistors. The low capacitance of the address and control inputs precludes the need for specialized drivers. The data input and output are multiplexed to facilitate compatibility with a common bus system.



The μPD418 has only one clock (chip enable), to simplify system design. The low capacitance clock input requires a positive voltage (+12 volts) which can be driven by a variety of widely available drivers.

FEATURES

- 4096 words x 1 bit Organization
- High Memory Density – 18 Pin Cerdip and Plastic Package
- 10% Supply Margins
- Multiplexed Data Input/Output
- High Speed Access, Low Power Dissipation (370 mW Max)
- Full TTL Compatibility on All Inputs (except CE)
- Resistors for Address Inputs Provided on Chip
- Open Drain Output Buffer
- Single Low Capacitance Clock (CE)
- Power Supply +12V, –5V
- Replacement for TI's 4050 and Equivalent Devices
- 3 Performance Ranges:

	ACCESS TIME	R/W CYCLE	RMW CYCLE	POWER (TYP)
μPD418D	300 ns	470 ns	650 ns	200 mW
μPD418D-1	250 ns	430 ns	610 ns	200 mW
μPD418D-2	200 ns	400 ns	580 ns	200 mW

READ CYCLE

WRITE CYCLE

READ-MODIFY-WRITE CYCLE

Notes:
① V_{DD} – 2V is the reference level for measuring timing of CE.
② V_{SS} + 2V is the reference level for measuring timing of CE.
③ V_{IH} MIN. is the reference level for measuring timing of addresses, R/$\overline{W}$, I/O (Write cycle).
④ V_{IL} MAX. is the reference level for measuring timing of addresses, R/$\overline{W}$, I/O (Write cycle).
⑤ V_{OH} MIN. is the reference level for measuring timing of I/O (Read cycle).
⑥ V_{OL} MAX. is the reference level for measuring timing of I/O (Read cycle).
⑦ During the time from the rise of CE to the fall of R/$\overline{W}$, R/$\overline{W}$ is permitted to change from high to low only.
⑧ If R/$\overline{W}$ remains high more than t_h(wr) from CE goes to high, the Data in driver must be disabled until R/$\overline{W}$ goes to low. (See Note 9.)
⑨ In region 1, Data out is valid until the I/O terminal is forced high or low by the data in driver. A transition from low to high is permissible but additional power to overcome the output buffer will be required. A transition from high to low is permitted without power penalty. In region 2, during the time from the fall of R/$\overline{W}$ to (t_f(R/$\overline{W}$) + 50 ns, MAX.), a transition from low to high permissible but additional power to overcome the output buffer will be required.

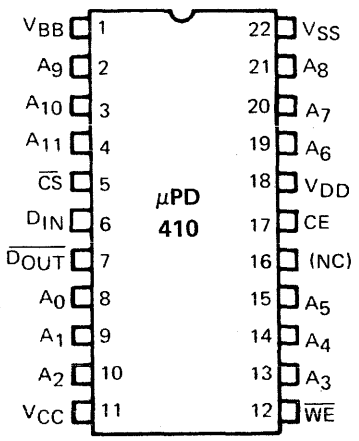
4096 BIT HIGH SPEED STATIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

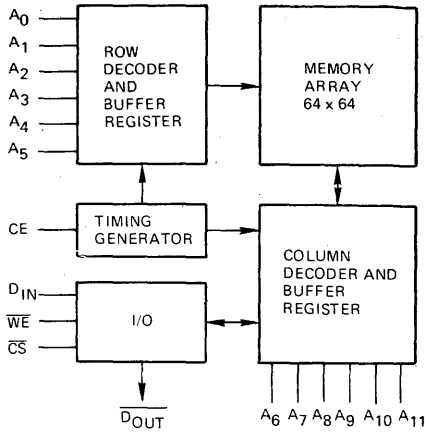
The μPD410 is a very high speed 4K bit static random access memory. It is organized as 4096 words by 1 bit per word and fabricated using N channel silicon gate MOS technology.



All signals to the device are TTL compatible except for Chip Enable which is standard +12 Volt MOS level.

Circuit operation starts with the rising edge of CE. Data is latched and valid until falling edge of CE. Address and Chip Select signals are latched on-chip to simplify system timing requirements.

FEATURES



- 4096 Words x 1 Bit Organization
- Fully Decoded
- TTL Compatible (except CE)
- High Speed-Access Time: 100 ns max.
- Cycle Time: 220 ns min.
- Static Operation — No Refresh Required
- Standby Power: 75 mW max.
- Active Power: 470 mW typ.
- Supply Voltages: V_{DD} = +12V, V_{CC} = +5V, V_{BB} = -5V
- Address Registers on the Chip
- Three State Output
- Standard 22 Pin Ceramic Dual-in-Line Package
- Pin Compatible with μPD411 and Other 4K Dynamic RAMs

PIN CONFIGURATION

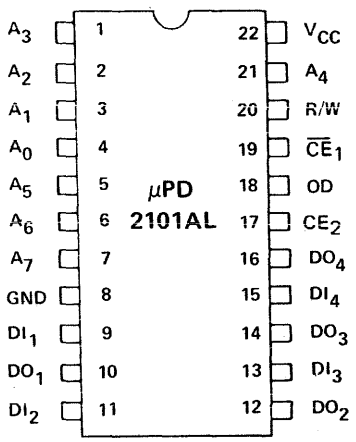
μPD2101AL-4

1024 BIT (256 X 4) STATIC MOS RAM WITH SEPARATE I/O

DESCRIPTION

The μPD2101ALC is a 256 word by 4 bit static random access memory requiring no clocks or refreshing. It features high speed, low cost, and simplicity of interfacing.

It is directly TTL compatible in all respects; inputs, outputs, and a single +5V supply. Two chip-enables allow easy selection of an individual package when outputs are OR-tied. An output disable is provided so that data inputs and outputs can be tied for common I/O systems. The output disable function eliminates the need for bidirectional logic in a common I/O system. Output data is the same polarity as input data, and readout is non-destructive.



The μPD2101ALC family of devices offers access times from 450 ns to 250 ns with a typical standby mode power dissipation of only 36 mW.

The use of NEC's N-channel silicon gate MOS process, with its excellent protection from contamination, permits the use of a low cost 22 pin plastic package in providing a high performance, high reliability MOS circuit at a most cost effective price level. The μPD2101ALC is pin-compatible with the μPD5101C CMOS static RAM.

FEATURES

- 256 x 4 Organizations to Meet Needs for Small System Memories
- Access Time – 250 to 450 nsec max
- Directly TTL Compatible – All Inputs and Output
- Static MOS – No Clocks or Refreshing Required
- Simple Memory Expansion – Chip Enable Input
- Low Standby Power – 36 mW typ.
- Low Cost Packaging – 22 Pin Plastic Dual-in-Line Configuration
- Low Operating Power
- Three-State Output – OR-Tie Capability
- Output Disable Provided for Ease of Use in Common Data Bus Systems

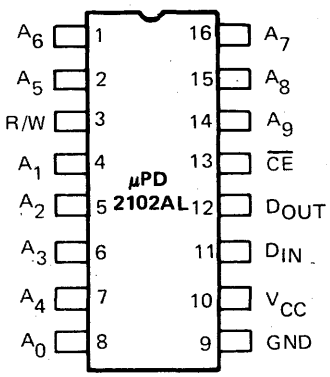
1024 BIT FULLY DECODED STATIC MOS RANDOM ACCESS MEMORY

DESCRIPTION

The μPD2102AL is a 1024 words by one bit static Random Access Memory requiring no clocks or refreshing. A family of devices with maximum access times ranging from 250 ns to 450 ns meet the requirements of microcomputer memory applications where speed, low cost and easy interfacing are prime design objectives.



All μPD2102AL inputs and outputs are TTL compatible. A single chip-enable ($\overline{CE}$) pin is provided for selection of an individual device in systems with OR-tied outputs. Output data is the same polarity as input data and is nondestructively read out. Only a single +5 volt supply is required. In standby mode, with the supply lowered to 1.5 volts, power dissipation is reduced to 42 mW max.

The μPD2102AL family is fabricated using NEC's N-channel MOS silicon gate process, providing excellent contamination protection. This process permits the use of a low cost plastic package (16 pin) and enables high performance, highly reliable MOS circuits to be produced.

FEATURES

- Access Time – μPD2102AL-2 – 250 ns Max
  μPD2102AL – 350 ns Max
  μPD2102AL-4 – 450 ns Max
- Single +5 Volts Supply Voltage
- Directly TTL Compatible – All Inputs and Output
- Static MOS – No Clocks or Refreshing Required
- Low Power – Typically 150 mW
- Low Standby Power – 42 mW max
- Three-State Output – OR-TIE Capability
- Simple Memory Expansion – Chip Enable Input
- Fully Decoded – On Chip Address Decode
- Inputs Protected – All Inputs have Protection against Static Charge
- Low Cost Packaging – 16 Pin Plastic Dual-In-Line Configuration

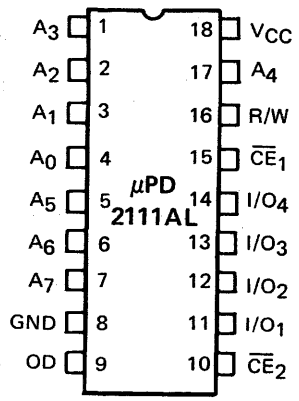
μPD2111AL
μPD2111AL-2
μPD2111AL-4

1024 BIT (256 x 4) STATIC MOS RAM WITH COMMON I/O AND OUTPUT DISABLE

DESCRIPTION

The μPD2111AL is a 256 words by 4 bits static random access memory fabricated with N-channel MOS technology. It uses fully static circuitry and therefore requires no clocks or refreshing to operate. The data is read out nondestructively and has the same polarity as the input data. Common input/output pins are provided.



It is directly TTL compatible in all respects: inputs, outputs, and a single +5V supply. Separate chip enable ($\overline{CE}$) leads allow easy selection of an individual package when outputs are OR-tied.

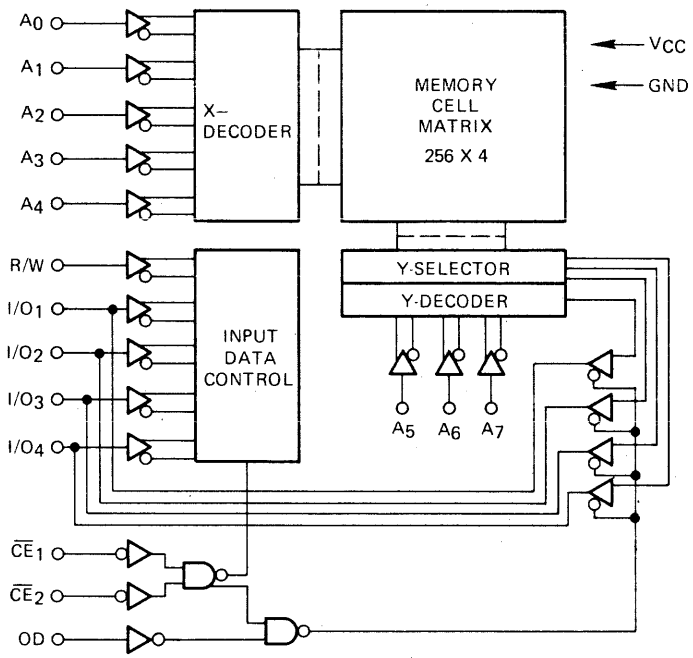
All members in the μPD2111AL family feature a low standby power mode with the supply voltage being reduced to +1.5V.

FEATURES

- 256 Words x 4 Bits Organization
- Common Data Input and Output
- Single +5V Supply Voltage
- Directly TTL Compatible — All Inputs and Outputs
- Static MOS — No Clocks or Refreshing Required
- Access Time — 250 ns to 450 ns max.
- Simple Memory Expansion — Chip Enable Inputs
- Fully Decoded — On Chip Address Decode
- Inputs Protected — All Inputs have Protection Against Static Charge
- Low Cost Packaging — 18 Pin Plastic Dual-In-Line Configuration
- Three-State Output — OR-Tie Capability
- Low Standby Power

PIN CONFIGURATION

PIN NAMES



A_0 - A_7	Address Inputs
OD	Output Disable
R/W	Read/Write Input
$\overline{CE}_1$	Chip Enable 1
$\overline{CE}_2$	Chip Enable 2
I/O_1 - I/O_4	Data Input/Output

OPERATION MODES

$\overline{CE}_1$	$\overline{CE}_2$	OD	Chip Output Status	
0	0	0	Selected	Data Output
0	0	1		High Z
Others			Unselected	State

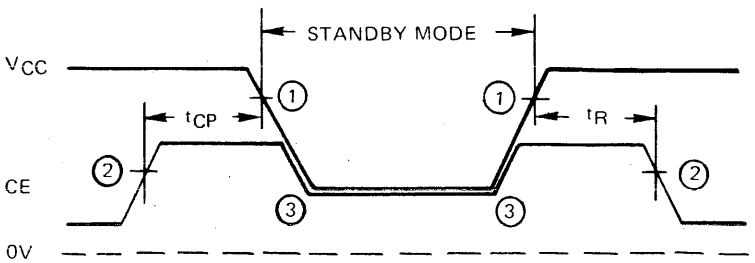
TIMING WAVEFORMS

READ CYCLE



Notes: ① OD should be tied low for separate I/O operation.
② R/W is high for read operation.

WRITE CYCLE

Note: OD is a logical 1 for common I/O and "don't care" for separate I/O operation.

STANDBY WAVEFORMS

Notes: ① 4.75V
② 2.0V
③ 1.5V
④ If the standby voltage (V_{PD}) is between 5.25V (V_{CC} Max) and 2.0V, then $\overline{CE}$ must be held at 2.0V Min (V_{IH}). If the standby voltage is less than 2.0V but greater than 1.5V (V_{PD} Min), then $\overline{CE}$ and standby voltage must be at least the same value or, if they are different, $\overline{CE}$ must be the more positive of the two. $\overline{CE}$ may be either of $\overline{CE}_1$ or $\overline{CE}_2$.

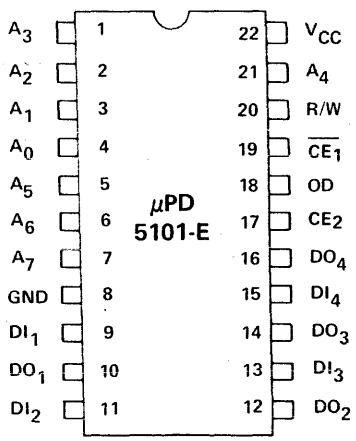
1024 BIT (256x4) STATIC CMOS RAM

DESCRIPTION

The μPD5101-E is a very low power 1024 bit (256 words by 4 bits) static CMOS Random Access Memory. It meets the low power requirements of battery operated systems and can be used to ensure non-volatility of data in systems using battery backup power.

All inputs and outputs of the μPD5101-E are TTL compatible. Two chip enables ($\overline{CE}_1$, CE_2) are provided, with the device being selected when $\overline{CE}_1$ is low and CE_2 is high. The μPD5101-E can be placed in standby mode, drawing 15 μA maximum, by driving $\overline{CE}_1$ high and inhibiting all address and control line transitions. The standby mode can also be selected unconditionally by driving CE_2 low.



The μPD5101-E has separate input and output lines. It can be used in common I/O bus systems through the use of the OD (Output Disable) pin and OR-tying the input/output pins. Output data is the same polarity as input data and is non-destructively read out. Read mode is selected by placing a high on the R/W pin. The μPD5101-E is guaranteed to retain data with the power supply voltage as low as 2.0 volts. Normal operation requires a single +5 volt supply.

The μPD5101-E is fabricated using NEC's complementary MOS (CMOS) process and is packaged in a 22-pin dual-in-line package.

FEATURES

- Directly TTL Compatible – All Inputs and Outputs
- Three-State Output
- Access Time – 800 ns
- Single +5V Power Supply
- CE_2 Controls Unconditional Standby Mode

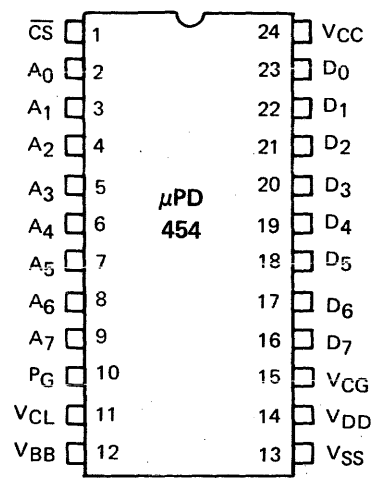
FULLY DECODED 2048 BIT ELECTRICALLY ERASABLE AND PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The μPD454 EEPROM, a 256 Words x 8 Bits Read Only Memory, is designed for rapid development of microcomputer systems. The ability to electrically program, erase, and reprogram the μPD454 provides a fast and convenient means of debugging both hardware and software designs.

The μPD454 is pin for pin compatible with NEC's μPD464 mask programmed ROM.

FEATURES

- Electrically Erasable and Programmable
- Fully Decoded, 256 Words x 8 Bits Organization
- Access Time 800 ns Max
- Low Power: 245 mW (Typ.) in Read Operation
  670 mW (Typ.) in Programming Operation
- Fast Programming and Erasure Speed
- Low Power for Programming and Erasure
- Static, No Clock Required
- Input/Output TTL Compatible for Read and Programming Operation
- Three-State Output, OR-Tie Capability
- N-Channel MOS Fabrication
- Two Power Supplies, +12V and +5V for Read Operation
- 24 Pin Ceramic DIP

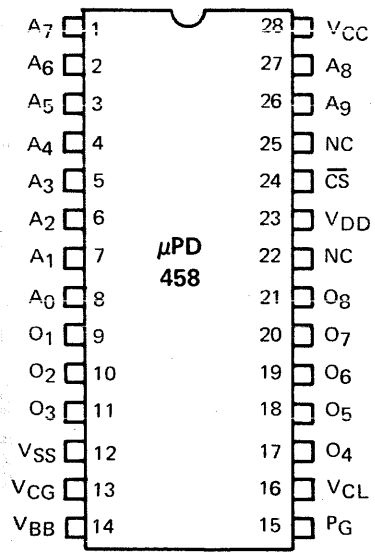
FULLY DECODED 8192 BIT ELECTRICALLY ERASABLE AND PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION

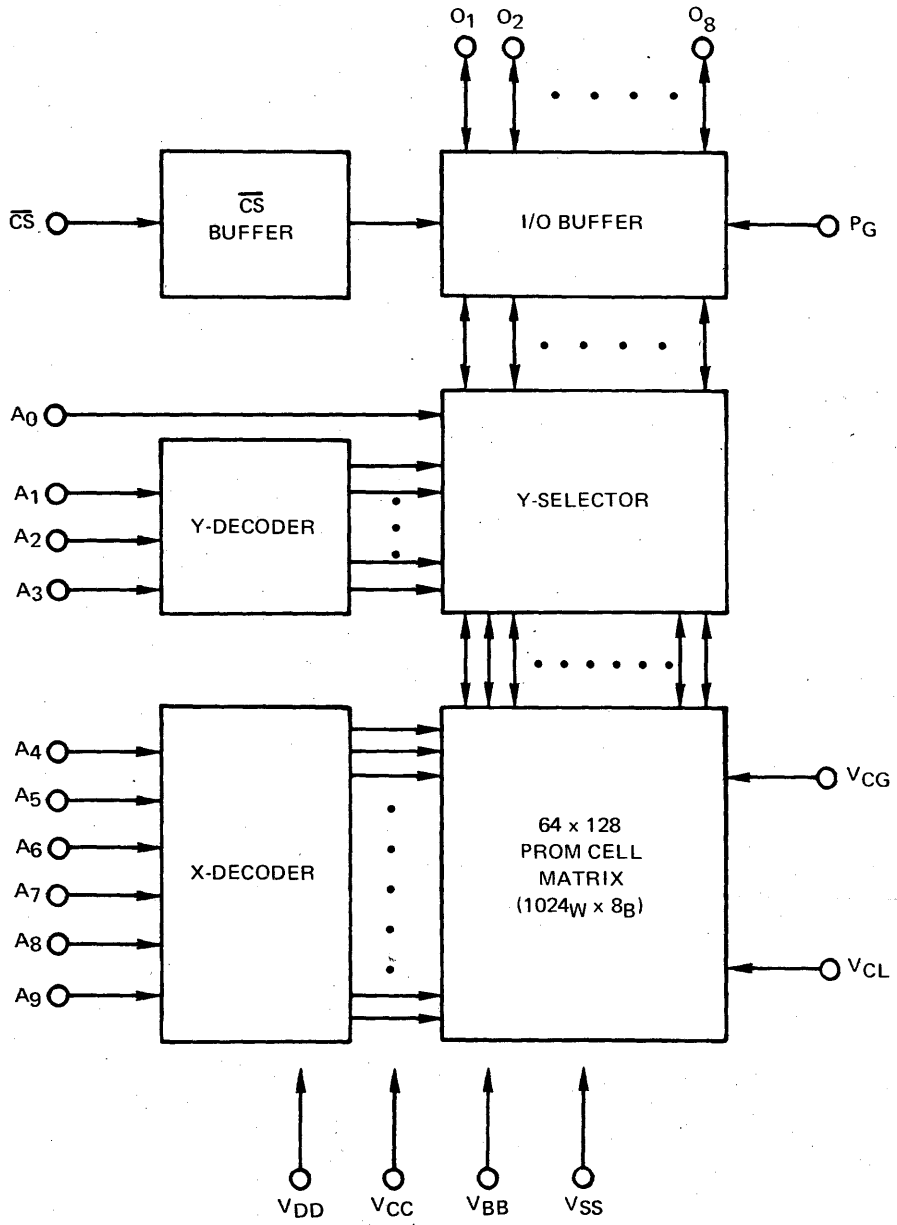


The μPD458 is an Electrically Erasable and Reprogrammable Read Only Memory (EEPROM), organized as 1024 words by 8 bits.

The μPD458 is fabricated with N-channel MOS technology and is packaged in a 28 pin ceramic DIP.

FEATURES

- Electrically Erasable and Reprogrammable
- Fully Decoded, 1024 Words x 8 Bits Organization
- Access Time – 450 ns max.
- Fast Programming and Erasure Speed
- Simple Worst-case Verification of Programmed Data and Erasure
- Static, No Clock Required
- Input/Output TTL Compatible for Read and Programming Operation
- Three-State Output, OR-Tie Capability
- N-Channel MOS
- Two Power Supplies, +12V and +5V for Read
- 28 Pin Ceramic DIP



PIN CONFIGURATION

NC: No Connection

PROGRAMMING OPERATION

Programming is performed word by word and one word at a time. Address and an 8 bit programming word for that address should be input at the same time. High level data "1" given through one of Data Input terminals ($O_1 - O_8$) writes a high level data "1" into the memory cell specified with the address input and its bit position.

After erasure, all memory cells of the μPD458 contain cleared data "0" By this programming operation, only the memory cells which contain data "0" are programmed to high level data "1" by high level input. Thus before normal programming operation, the μPD458 should undergo erasure operation to clear all bits to "0".

DC CHARACTERISTICS

$T_a = 25°C \pm 2°C$, $V_{DD} = V_{CC} = V_{SS} = V_{CL} = 0V$. $\overline{CS}$ = Either HIGH or LOW level.

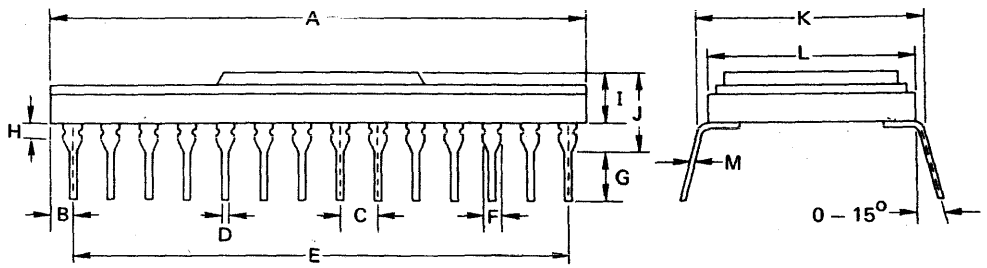
APPENDIX
PROM PROGRAMMER
DESIGN

To insure integrity and retention of data programmed in the μPD458, the following requirements are specified for the μPD458 supply voltage and current levels. The PROM PROGRAMMER should be designed such that voltages provided to the PROM socket be within the range specified on any occasion including power on/off to the programmer, power on/off to the μPD458, and in READ, WRITE or ERASE operation. Surge or noise voltages beyond the specified range are to be avoided.



Setting V_{DD} = +12V ± 5%, V_{CC} = +5V ± 5% and V_{CG} = +3V ± 0.1V after erasure and comparing data read from the μPD458 with zero effectively tests for proper erasure.

Setting V_{DD}= +12V ± 5%, V_{CC} = +5V ± 5% and V_{CG} = -3V ± 0.1V after programming and comparing data read from the μPD458 with the desired data coupled with erase verification, provides a simple test of worst-case temperature and long-term data retention.

Under normal Read Mode conditions, V_{CG} should either be grounded directly or held at 0V ± 0.1V through R_{CG}. R_{CG} is required when any non-zero voltage is applied to V_{CG}.

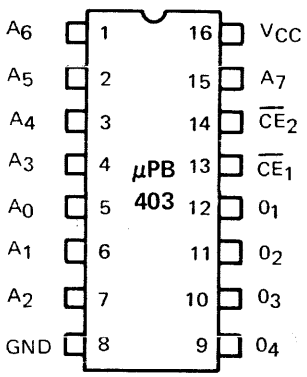
1024-BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY



DESCRIPTION

The μPB403 is a high speed electrically programmable fully decoded 1024 bit TTL read only memory. On-chip address decoding, two chip enable inputs and open-collector outputs allow easy expansion of memory capacity. The μPB403 is fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the selected bit locations. The same address inputs are used for both programming and reading.

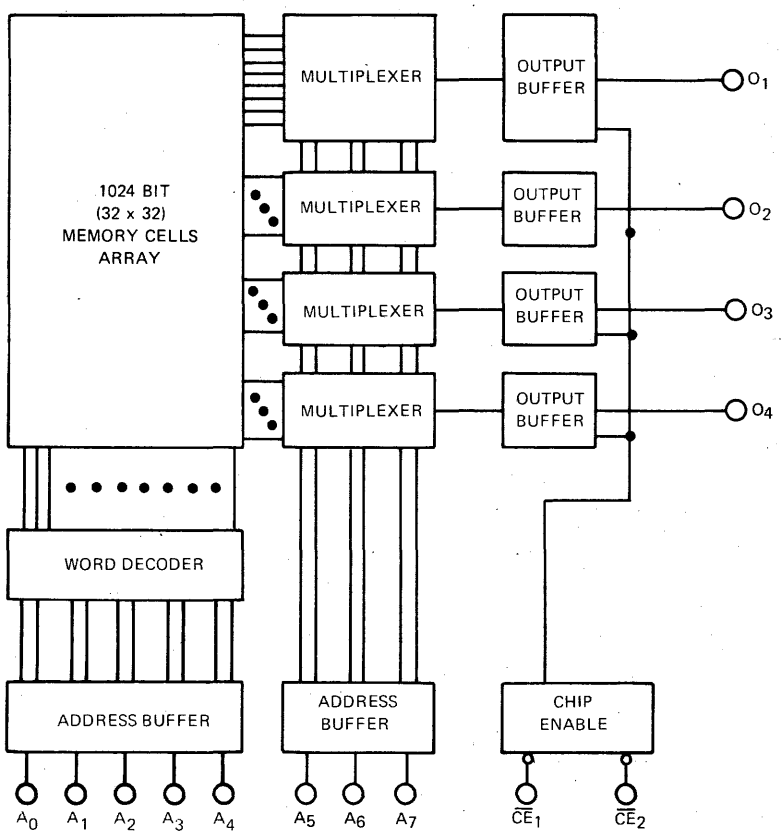
FEATURES

- 256 Words x 4 Bits Organization (Fully Decoded)
- TTL Interface
- Fast Read Access Time: 30 ns TYP.
- Medium Power Consumption: 450 mW TYP.
- AIM (Avalanche Induced Migration) Technology
- Two Chip Enable Inputs for Memory Expansion
- Open-Collector Outputs
- Ceramic 16-Pin Dual-In-Line Package
- Fast Programming Time: 200 μs/bit TYP.
- Compatibility with: Intersil's IM5603A (both in programming and as a ROM), Harris HPROM1024A and Equivalent Devices (as a ROM)

PIN CONFIGURATION

©IC MASTER 1978

OPERATION



Programming

A logic one can be permanently programmed into a selected bit location in accordance with the programming procedures specified. First, the desired word is selected by the eight TTL address inputs. Either or both of the two chip enable inputs should be at a logic one (high). Secondly, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, and programming is complete.

Reading

To read the memory, both of the two chip enable inputs should be held at logic zero (low). The outputs then correspond to the data programmed in the selected words. When either or both of the two chip enable inputs are at logic one (high), all the outputs will be high (floating).

PROGRAMMING SPECIFICATION

It is imperative that this specification be rigorously observed in order to correctly program the μPB403. NEC will not accept responsibility for any device found to be defective if it were not programmed according to this specification.

A typical programming operation is performed by first sensing, then programming, then sensing again to see if the word to be programmed has reached the desired state.

Sensing is accomplished by forcing a 20 mA current into the selected location via the output. The μPB403 is disabled by forcing 2 mA into one of the chip enables. The sense measurement is to ensure that the voltage required to force this 20 mA current is less than the reference voltage. If this condition is satisfied, then that bit location is in the logic "1" (high) state.

Programming is accomplished by forcing a 200 mA current into the selected bit via the output. This operation is also executed with 2 mA being forced into a chip enable. This current pulse is applied for 7.5 μs and then the location is sensed before a second programming current pulse is applied. This process is continued until that location is altered to the "1" state. A bit is judged to be programmed when two successive sense readings 10 μs apart with no intervening programming pulse, pass the limit. When this condition has been met, four additional pulses are applied and the pulse train, then the sense current is terminated.

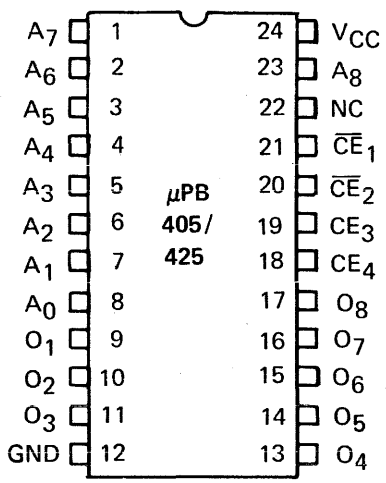
4096-BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY



DESCRIPTION

The μPB405 and μPB425 are high speed, electrically programmable, fully decoded 4096-bit TTL read only memories. On-chip address decoding, four chip enable inputs and open-collector outputs allow easy expansion of memory capacity. The μPB405 and μPB425 are fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the selected bit locations. The same address inputs are used for both programming and reading.

FEATURES

- 512 WORDS X 8 BITS Organization (Fully Decoded)
- TTL Interface
- Fast Read Access Time: 70 ns max. (μPB425)
- Medium Power Consumption: 600 mW TYP.
- Four Chip Enable Inputs for Memory Expansion
- Open-Collector Outputs (μPB405)/Three-State Outputs (μPB425)
- Ceramic 24-Lead Dual In-Line Package
- Fast Programming Time: 200 μs/bit TYP.
- Compatibility with: Intersil's IM5605/5625 (both in programming and as a ROM), Harris' HPROM HM-7640/7641 and Equivalent Devices (as a ROM).
- A.I.M. (Avalanche Induced Migration) Technology

PIN CONFIGURATION

NC: No Connection

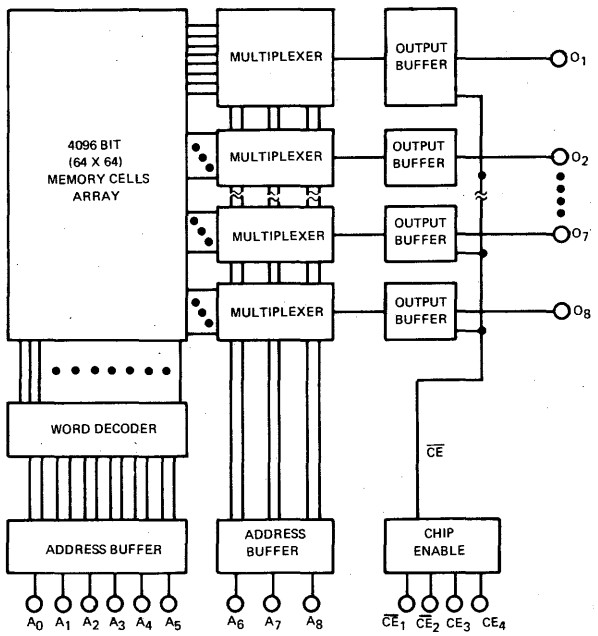
©IC MASTER 1978

OPERATION

Chip Enable logic is defined by:

$\overline{CE}_1$	$\overline{CE}_2$	CE_3	CE_4	CE'
0	0	1	1	0
All other combinations				1

Where: CE' = 0 denotes chip selected
CE' = 1 denotes chip deselected



Programming

A logic one can be permanently programmed into a selected bit location in accordance with the programming procedures specified. First, the desired word is selected by the eight TTL address inputs. The four Chip Enable inputs must be set so that CE' is a logical one. Secondly, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, and programming is complete.

Reading

To read the memory, the four Chip Enable inputs must be set so that CE' is a logical zero. The outputs then correspond to the data programmed in the selected words. When the four Chip Enable inputs are set so that CE' becomes a logical one, all the outputs will be high (floating).

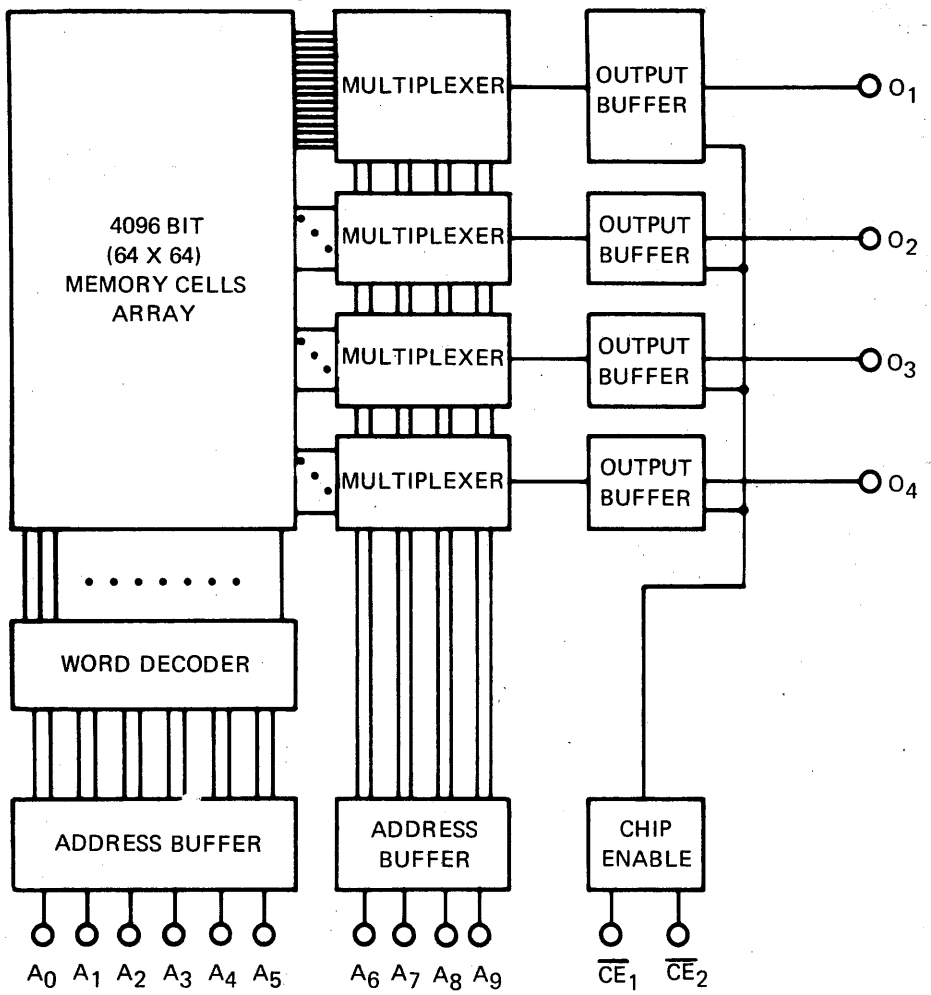
OPERATION



Programming

A logic one can be permanently programmed into a selected bit location by using special equipment (programmer). First, the desired word is selected by the ten address inputs in TTL levels. Either or both of the two chip enable inputs must be at a logic one (high). Secondly, a train of high current programming pulses is applied to the desired output. After the sensed voltage indicates that the selected bit is in the logic one state, an additional pulse train is applied, then is stopped.

Reading

To read the memory, both of the two chip enable inputs should be held at logic zero (low). The outputs then correspond to the data programmed in the selected words. When either or both of the two chip enable inputs are at logic one (high), all the outputs will be high (floating).

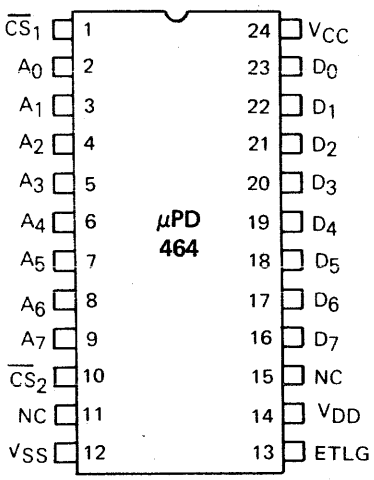
FULLY DECODED 2048 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION

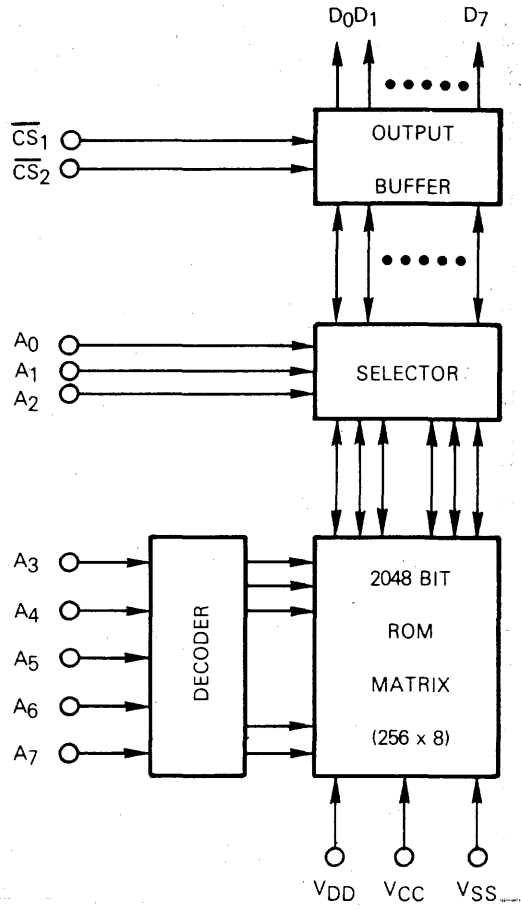
The μPD464 is a 2048 bit (256 x 8) mask programmable Read Only Memory. It is pin-for-pin compatible with NEC's Electrically Eraseable Programmable ROM (EEPROM), the μPD454. The μPD464 features high speed operation, making it suitable for large volume microcomputer memory applications that used the μPD464 for initial prototyping.



All inputs and outputs of the μPD464 are TTL compatible. Two chip select pins ($\overline{CS}_1$, $\overline{CS}_2$) are provided for selection of an individual device in systems with OR-tied outputs. Two power supplies, +12 volts and +5 volts, are required.

The μPD464 is fabricated using NEC's N-channel MOS silicon gate process, providing excellent contamination protection. This process enables high performance, highly reliable MOS circuits to be produced. The μPD464 is packaged in a 24-pin ceramic or plastic dual-in-line package.

FEATURES



- Fully Decoded, 256 Words x 8 Bits Organization
- Access Time 450 ns Max.
- Static, No Clock Required
- Input/Output TTL Compatible
- Three-State Output, OR-Tie Capability
- N-Channel MOS Fabrication
- Two Power Supplies, +12V and +5V
- 24 Pin Ceramic or Plastic DIP

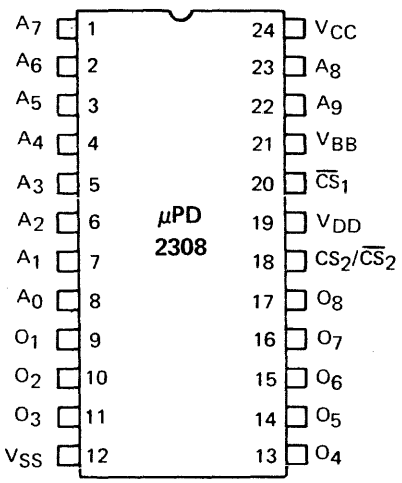
FULLY DECODED 8192 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The NEC μPD2308 is a high speed 8,192 bit mask programmable Read Only Memory organized as 1024 words by 8 bits. The μPD2308 is fabricated with N-channel MOS technology.

Two Chip Selects are provided – $\overline{CS}_1$ which is negative true, and $CS_2/\overline{CS}_2$ which may be programmed either negative or positive true at the mask level.

FEATURES

- 1024 Words by 8 bits Organization
- Fast Access – 450 ns max
- Two Chip Select Inputs for Easy Memory Expansion
- TTL Compatible – All Inputs and Outputs
- Three State Output – OR-Tie Capability
- Fully Decoded
- Standard Power Supplies – +12V, ±5V
- 24 Pin Plastic or Ceramic Dual-in-Line Package
- Pin Compatible with INTEL 8308

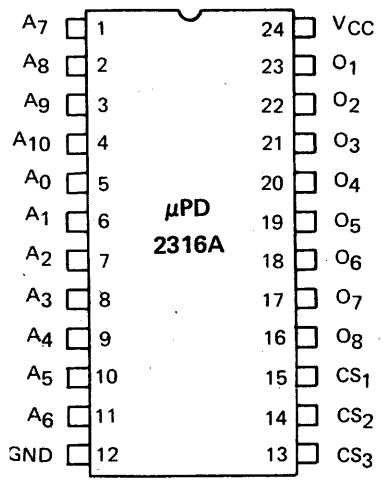
FULLY DECODED 16,384 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



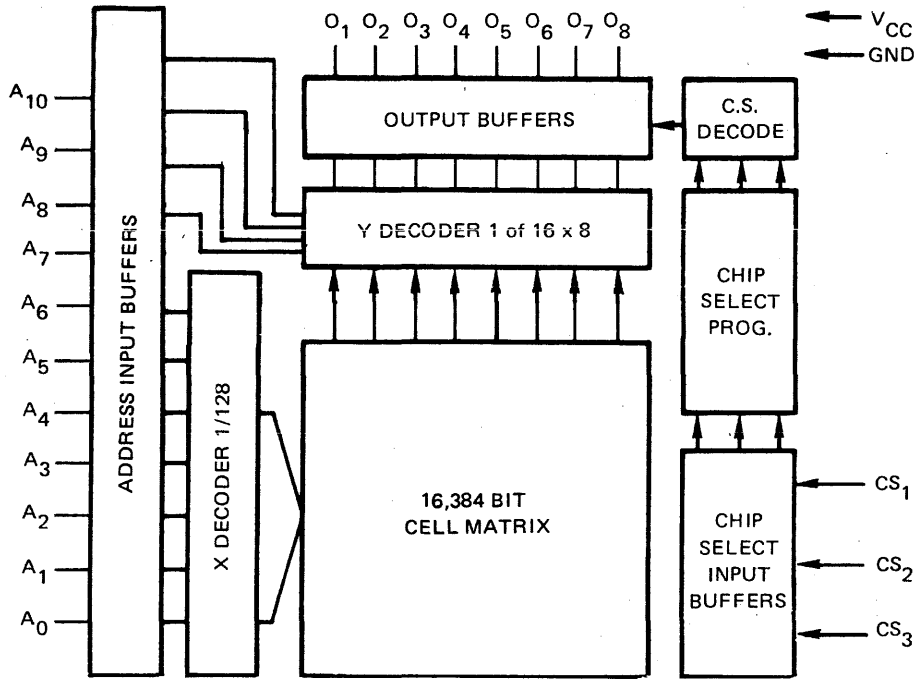
The NEC μPD2316A is a high speed 16,384 bit mask programmable Read Only Memory organized as 2048 words by 8 bits. The μPD2316A is fabricated with N-channel MOS technology.

The inputs and outputs are fully TTL compatible. The device operates with a single +5V power supply. The three chip select inputs are programmable. Any combination of active high or low level chip select inputs can be defined and desired chip select code is fixed during the masking process.

FEATURES

- Access Time 450 ns Max
- 2048 Words x 8 Bits Organization
- Single +5V Power Supply Voltage
- Directly TTL Compatible – All Inputs and Outputs
- Three Programmable Chip Select Inputs for Easy Memory Expansion
- Three-State Output – OR-Tie Capability
- On Chip Address Fully Decoded
- All Inputs Protected Against Static Charge
- Direct Replacement for Intel 2316A/8316A
- Available in 24-pin plastic or ceramic package.

PIN CONFIGURATION



PIN NAMES

$A_0 - A_{10}$	Address Inputs
$O_1 - O_8$	Data Outputs

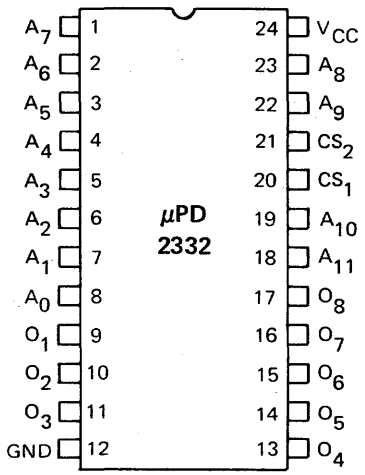
FULLY DECODED 32,768 BIT MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION



The NEC μPD2332 is a Fully Decoded 32,768 Bit Mask Programmable Read-Only Memory organized as 4,096 Words by 8 Bits. The μPD2332 has two chip select inputs and the combination of "High"/"Low" levels of these inputs is mask-programmable.

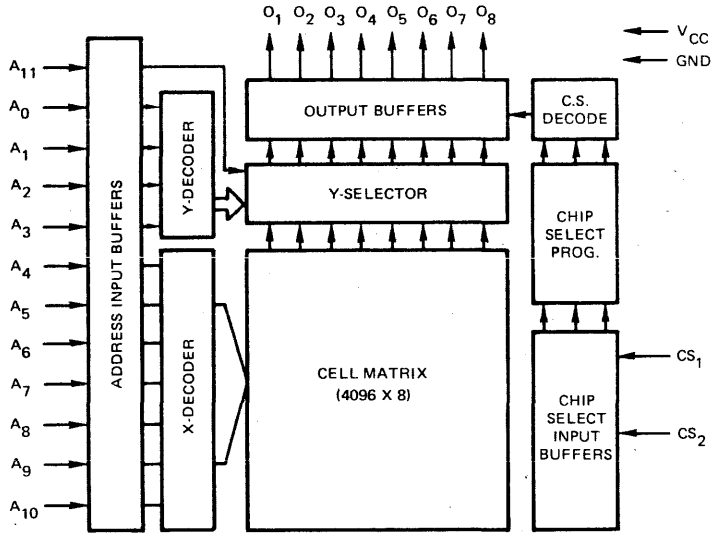
The μPD2332 is fabricated with sophisticated N-channel MOS technology and features high speed and TTL compatibility for simple interface with bipolar circuits.

FEATURES

- 4096 Words x 8 Bits Organization
- Directly TTL Compatible – All Inputs and Outputs
- Fully Static (No Clock or Refresh Required)
- Single +5V Power Supply
- High Speed – Access Time 450 ns Max.
- Three-State Output – OR-Tie Capability
- Two Programmable Chip Select Inputs for Easy Memory Expansion
- N-Channel MOS Technology
- Pin Compatible with TI TMS4732
- 24 Pin Plastic or Ceramic Dual-in-Line Package

PIN CONFIGURATION

PIN NAMES



$A_0 - A_{11}$	Address Inputs
$O_1 - O_8$	Data Outputs
$CS_1 - CS_2$	Programmable Chip Select Inputs

When ordering the μPD2332, specify a chip select combination of CS_1 and CS_2 from the following.

CS_2	CS_1
0	0
0	1
1	0

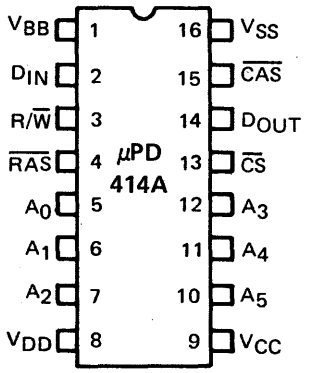
4K BIT DYNAMIC RAM



DESCRIPTION

The NEC μPD414A is a 4096 words by 1 bit dynamic Random Access Memory fabricated with N-channel MOS technology. It features high performance, low power, and 16 pin packaging for high system bit density. The 12 bit address is multiplexed into the chip in two 6 bit halves. Flexible I/O control allows common or separate I/O data busses.

FEATURES

- Four speeds: 300 ns (μPD414A)
  250 ns (μPD414A-1)
  200 ns (μPD414A-2)
  150 ns (μPD414A-3)
- ±10% Supply Tolerance
- Gated $\overline{CAS}$ Operation
- Latched Output
- Three State Output
- Fully TTL Compatible
- Replacement for 4027 Type Devices

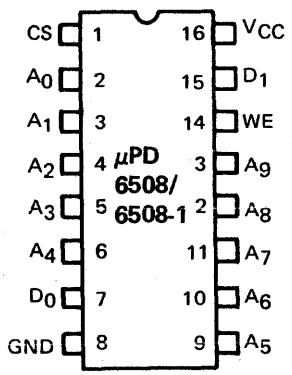
1K (1024x1) STATIC CMOS RAM



DESCRIPTION

The NEC μPD6508/6508-1 are high speed, low power, silicon gate CMOS RAMs organized as 1024 words by 1 bit. It features extremely low power requirements and data retention to +3 volts V_{CC}.

FEATURES

- Extremely Low Power Operation
- High Speed – 250 ns Max (μPD6508-1)
- TTL Compatible, All Inputs and Outputs
- Static Operation
- On Chip Register Address
- Replacement for 5608 Type Devices

4K (1024x4) STATIC RAM

DESCRIPTION

The NEC μPD2114 is a 4096 bit, fully static Random Access Memory, organized as 1024 words by 4 bits. It is fabricated with N-channel silicon gate technology and is housed in an 18 pin package for high system bit densities.

PIN CONFIGURATION

FEATURES

- High Density 18 Pin Package
- Completely Static
- Directly TTL Compatible — All Inputs and Outputs
- Single +5V Supply
- Low Operating Power — 0.06 mW/Bit Typ
- Access Time — 250 ns Typical

μPB2400
μPB2401

4096 BIT STATIC BIPOLAR RAM

DESCRIPTION

The NEC μPB2400 and μPB2401 are static, Random Access Memories organized as 4096 words by 1 bit. The devices feature operation from a single +5 volt supply, and are fully TTL compatible. Fast data out disable time allows a common I/O data bus structure.

PIN CONFIGURATION

FEATURES

- 4096 Words x 1 Bit Organization
- Fast Read and Write Cycle — 75 ns Typ
- Low Power Operation — 500 mW Typ
- Single +5 Volt Supply
- 18 Pin Cerdip Package
- Latched Data Outputs
- Three State (μPB2401) or Open Collector (μPB2400) Output
- Replacement for 74S400/401

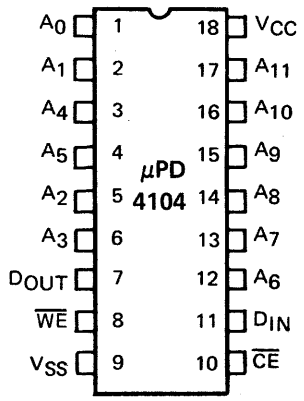
4096 × 1 STATIC NMOS RAM



DESCRIPTION

The NEC μPD4104 is a high speed 4096 bit Static RAM organized as 4096 words by 1 bit. The use of static storage circuitry eliminates the need for refresh while the dynamic control circuitry provides substantially lower power dissipation than fully static types.

FEATURES

- Fast Access Time – 200 ns
- High System Density – 18 Pin Package
- Fully TTL Compatible – All Inputs and Outputs
- Single +5V Supply

PIN CONFIGURATION

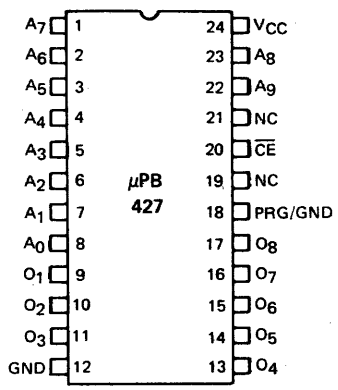
8192 BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION

The NEC μPB408 and μPB428 are high speed, electrically programmable, 8192 bit, TTL, Read Only Memories. Three chip enable inputs and three state (μPB428) or open collector (μPB408) outputs allow OR-tying outputs for ease of memory expansion. The devices are fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the desired bit locations.

PIN CONFIGURATION

FEATURES



- 1024 Words x 8 Bits Organization
- Fast Access Time - 85 ns Max
- Three State (μPB428) or Open Collector (μPB408) Outputs
- Replacement for 6380/6381 Type Devices

8192 BIT BIPOLAR TTL PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION

The NEC μPB427 is a high speed, electrically programmable, 8192 bit, TTL, Read Only Memory. Three-state outputs and a chip enable input allow easy expansion of memory capacity. The μPB427 is fabricated with logic level zero (low); logic level one (high) can be electrically programmed into the desired bit locations.

PIN CONFIGURATION

FEATURES

- 1024 Words x 8 Bits Organization
- Fast Read Access Time - 120 ns Max
- Power Switching - 750 mW Max Selected
  - 350 mW Max Unselected
- Three State Outputs
- Replacement for 2708 Type Devices as a ROM

μPD2316E

16K (2048x8) MASK PROGRAMMABLE READ ONLY MEMORY

DESCRIPTION

The NEC μPD2316E is a high speed 16,384 bit mask programmable Read Only Memory organized as 2148 words by 8 bits. All inputs and outputs are fully TTL compatible. These devices operate with a single +5V supply. The three chip select inputs are programmable; any combination of active high or low level chip select inputs can be defined and fixed during the masking process.

PIN CONFIGURATION

FEATURES

- Access Time - 450 ns Max
- 2048 Words x 8 Bits Organization
- Single +5V Supply
- Directly TTL Compatible
- Three Programmable Chip Selects
- Three State Outputs — OR-Tie Capabilities
- Direct Replacement for 2316E Type Devices

RAYTHEON THE NEW INNOVATOR IN PROGRAMMABLE MEMORY COMPONENTS

RAYTHEON

©IC MASTER 1978

POWER SWITCHED PROMS (SPROMS)

In June of 1977, Raytheon announced the first performance compatible PROMS with on-chip power switching. By simply de-selecting the SPROM, the typical power requirements are reduced from 70-80% depending on whether the device is an open-collector or tri-state version. In large PROM arrays, the direct substitution of the SPROM for the standard PROM can reduce the overall power consumption by more than 50%.

FEATURES

- Highly reliable nichrome fuses
- Three-state and open collector versions
- Standard PROM and SPROM (power switched) versions
- Standard pin outs
- Readily available programming equipment
- Available in both military and commercial temperature ranges
- Low current PNP inputs

PROGRAMMING INSTRUCTIONS

DEVICE DESCRIPTION

Raytheon PROMS are manufactured with all outputs high in all storage locations. To make an output low at a particular word, a nichrome fusible link must be changed from a low resistance to a high resistance. This procedure is called programming. Programming equipment can be obtained from Data I/O, Inc., and other manufacturers of P/ROM programming equipment.

PROGRAMMING DESCRIPTION

To select a particular fusible link for programming, the word address is presented with TTL levels on the address pins, a V_{CC} of 5.50V is applied or left applied, and the program pin (CS) and the output to be programmed are taken to an elevated voltage to supply the required current to program the fuse. The outputs must be programmed one output at a time, since internal decoding circuitry is capable of sinking only one unit of programming at a time.

TIMING

The programming procedure involves the use of the program pin (CS) and the output pin. In order to guarantee that the output transistor is off before increasing the voltage on the output pin, the program pin's voltage pulse must come before the output pin's programming pulse and leave after the output pin's programming pulse. 100 ns delay is adequate. The programming pulse applied to the output pin and program pin must have a 50 to 70 microseconds rise time. See Figure 1.

PROGRAMMING SPEED

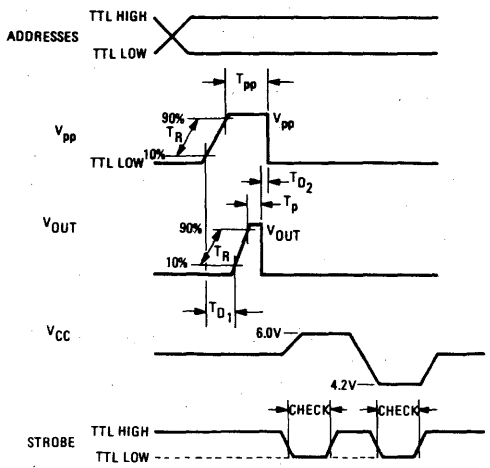
Typically fuses will blow on the rise time of the pulse.

In automated programmers which must copy devices in a short time because of production requirements, the following pulse and voltage sequences have been found to maximize reliability, programming yield, and thruput. The device should be verified after each programming attempt and is advanced to the next bit if the device has programmed.

PULSE NUMBER	PROGRAM PIN VOLTAGE	OUTPUT VOLTAGE
1 to 3	27V	20V
4 to 6	30V	23V
7 to 9	33V	26V

VERIFICATION

After programming either device, it can be checked for a low output by taking CS low. Since we must guarantee operation at minimum and maximum V_{CC}, current and temperature, the device must be required to sink 12 mA at 4.20V V_{CC} and 0.2 mA at 6.0V V_{CC} at room temperature.



BOARD PROGRAMMING

Units may be programmed at the board level by bringing the program pin of each package to the card connector. To program a particular package "A", the program pin of package A and one output of package A, which may or may not be "OR" tied to other packages, are taken to the required programming voltage. An alternate procedure is to tie the CS and outputs together as required by the system function and only apply V_{CC} to the device to be programmed. The number of units soldered on a board should be consistent with expected programming yields to avoid rework.

UNPROGRAMMABLE UNITS

Visual inspection at 200X prior to encapsulation, test fuses and decoding circuitry tests are used to guarantee a high programming yield of the devices in the field. However, because of random defects, it is impossible to guarantee that a link will open without actually programming it. **UNITS RETURNED TO RAYTHEON AS UNPROGRAMMABLE MUST BE ACCOMPANIED BY A COMPLETE DEVICE TRUTH TABLE WITH THE LOCATION WHICH CANNOT BE PROGRAMMED, OR WHICH FALSELY PROGRAMMED, CLEARLY INDICATED.**

RAYTHEON
©IC MASTER 1976

T_R 0.4 V/μs ±15%
T_{pp} 95 ±15 μs
T_p 1 μs min., 8 μs max.
T_{D_1} 80 ±10 μs
T_{D_2} 100 ns min.

NOTE: Output Load = 0.2 mA during 6.0V check
Output Load = 12 mA during 4.2V check

Figure 1. Program Timing

TRUTH TABLES

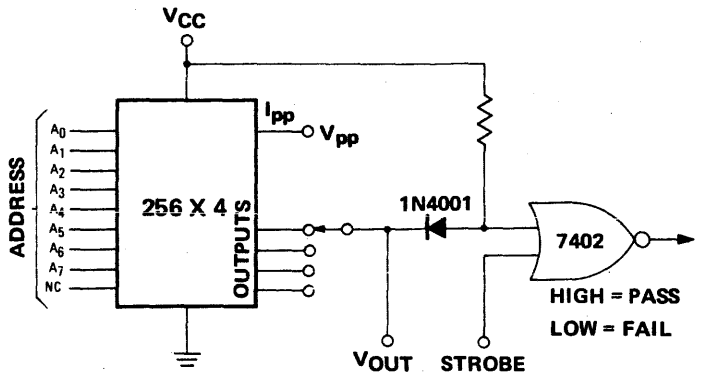
Raytheon can program devices at our facility from Raytheon truth table forms (available on request). For customers desiring to make their own forms, an example is shown below for a 256 x 4 device.

		OUTPUTS			
WORD NUMBER	PIN ⟶	9 O_4	10 O_3	11 O_2	12 O_1
0		H	H	H	L
1		L	H	L	H
.		.	.	.	.
.		.	.	.	.
255		L	H	H	H

Note: A high voltage on the data out lines is signified by an "H". A low voltage on the data out lines is signified by an "L". The word number assumes positive logic on the address pins, so for example, word 255 = HHHHHHHH.

PAPER TAPE FORMAT

Truth tables can also be sent to Raytheon in an ASCII tape format. Information can be sent to us by air mail or TWX 910-379-6481. The tape reading equipment at Raytheon only recognizes ASCII characters S, B, P, N, F, and E and interprets them as:



S	Start
B	Begin a word
P	High data
N	Low data
F	Finish a word
E	End of tape

All other characters such as carriage returns, line feeds, etc. are ignored so that comments and spaces may be sent in the data field to improve readability. Comments, however, should not use the characters S, B, P, N, F, and E. Word addresses must begin with zero and count sequentially to word the maximum number of words.

In order to assist the machine operator in determining where the heading information stops and the data field begins, 25 bell characters or rubout characters should precede the start of the truth table. Any type of 8 level paper tape (mylar, fanfold, etc.) is acceptable. Channel 1 is the most significant bit and channel 8 (parity) is ignored. Sprocket holes are located between channels 3 and 4. Note that the output between characters B and F starts with the most significant bit and ends with the least significant bit.

A typical list of characters and their machine interpretations are shown on the next page.

©IC MASTER 1978

Suggested Implementation of the Verification Circuitry

Notes:

1. For proper threshold adjustment, insert a 2N404 germanium transistor with collector and emitter shorted so that it looks like a diode in series with pin 7 of the 7402 to ground.
2. The 1N4001 diode protects the input of the 7402 from the high programming voltages.

X 4 Example

BEGIN DATA FIELD
DATA FIELD (H = HIGH VOLTAGE, L = LOW)
FINISHED DATA FIELD

B P P N P F B P P P P F B P N N P F – – – B P N N N F (etc)

O_4 O_3 O_2 O_1

WORD 0 WORD 1 WORD 2 WORD 511

X 8 Example

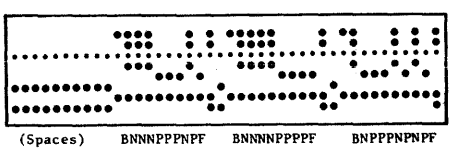
BEGIN DATA FIELD
DATA FIELD (H = HIGH VOLTAGE, L = LOW VOLTAGE)
FINISHED DATA FIELD

B P P P N P P N P F BPPPPPPPPF BPNPPPNNPF – – – BPPNPPNNNF (etc)

O_8 O_7 O_6 O_5 O_4 O_3 O_2 O_1

WORD 0 WORD 1 WORD 2 WORD 255

The required heading information at the beginning of the tape is as follows:



Customer name and phone_____ Truth table number_____
Customer TWX number_____ Number of truth tables_____
Purchase order number_____ Total number of parts_____
Raytheon part number_____ Number of parts of each truth table_____
Customer symbolized part number_____ 25 bell or rubout characters_____

An example is shown below:

PROGRAMMING PARAMETERS — Do not test these limits or you may program the device.

SYMBOL	PARAMETER	TEST CONDITIONS (See Figure 4)	LIMITS MIN.	LIMITS TYPICAL OR OPTIMUM	LIMITS MAX.	UNITS
I_{pp}	Current program pin during programming. Before and after fuse has blown	V_{CC} = 5.50V V_{out} = 5.0 to 25V V_{pp} = 4.50V		0		mA
		V_{pp} = 27V		77		mA
I_{out}	Current into output during programming before the fuse has programmed	V_{pp} = 27V, V_{CC} = 5.50V V_{out} = 9.0V		0.1		mA
		V_{out} = 20V		16		mA
I_{out}	Current into output during programming after the fuse has programmed.	V_{pp} = 27V, V_{out} = 20V V_{CC} = 5.50V		0.1		mA
T_R	Rise time of program pulse applied to the data out or program pin.		0.34	0.4	0.46	V/μs
V_{CCP}	V_{CC} required during programming.		5.40	5.50	5.60	V
I_{OLV1}	Output current required during verification.	Both chip enables low T_A = 25°C, V_{CC} = 4.2V	11	12	13	mA
I_{OLV2}	Output current required during verification.	Both chip enables low T_A = 25°C, V_{CC} = 6.0V	0.19	0.2	0.21	mA
MDC	Maximum duty cycle during automatic programming of program pin and output pin.	$\frac{T_P}{T_C}$			25	%
V_{pp}	Required programming voltage on program pin.		27	27	33	V
V_{out}	Required programming voltage on the output pin		20	20	26	V
I_L	Required current limit of the power supply feeding the program pin and and the output during programming.	V_{pp} = 33V V_{out} = 26V V_{CC} = 5.50V	150			mA
T_{pp}	Required coincidence among the program pin, output, address and V_{CC} for programming.		80	95	110	μs
T_{D1}	Required time delay between disabling the memory output and application of the output programming pulse.	Measure at 10% levels	70	80	90	μs
T_{D2}	Required time delay between removal of programming pulse and enabling the memory output.	Measure at 10% levels	100			nS

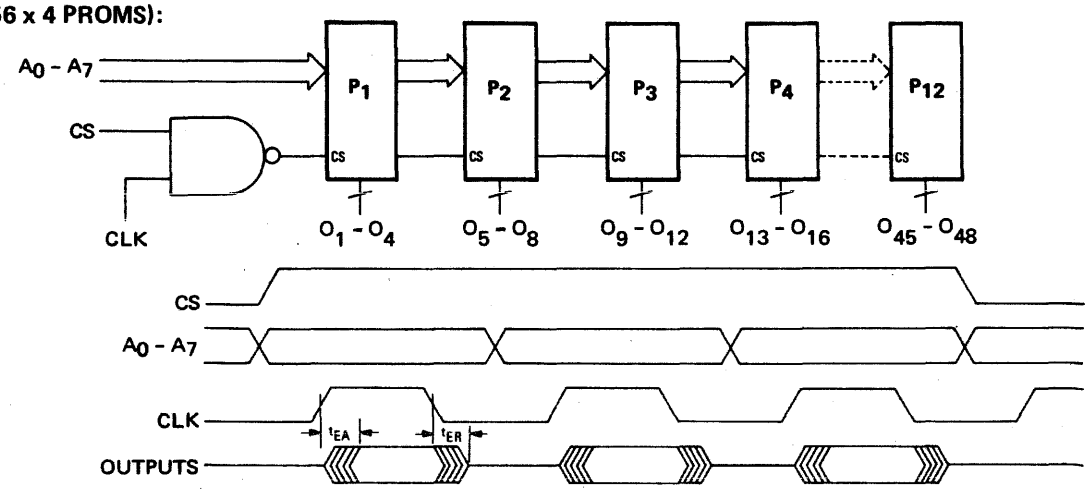
1024 X 16 BIT PROM ARRAY APPLICATION:
(Using 256 x 4 PROMS):

TYPICAL POWER DISSIPATION

Without Power Switching:

16 devices X 450 mW/device = 7.2 watts



With Power Switching (29662):

4 devices X 450 mW/device = 1.8 watts

12 devices X 100 mW/device = 1.2 watts

Total Power = 3.0 watts

256 X 48 BIT CLOCKED PROM APPLICATION:
(Using 256 x 4 PROMS):

TYPICAL POWER DISSIPATION

Without Power Switching:

12 devices X 450 mW/device = 5.4 watts

With Power Switching (29662 and 50% duty cycle clock):

(0.5 X 12 devices X 450 mW/device) + (0.5 X 12 devices X 100 mW/device) = 3.3 watts

With Power Switching (29662 and 20% duty cycle clock):

(0.2 X 12 devices X 450 mW/device) + (0.8 X 12 devices X 100 mW/device) = 2.04 watts

INTRODUCTION TO MICROPROCESSORS

This section briefly describes microprocessors from 26 manufacturers. It gives you a list of system components (pages 1504-1513) followed by detailed information from the manufacturers on key products (pages 1537-1927).

The extent of information, support, and applications assistance available from manufacturers is an important factor in selecting microprocessors. Therefore, the detailed facts presented in the system descriptions include hardware and software items. The descriptions indicate whether complete operating cards are offered and indicate if "prototyping systems" or developmental operating systems are available. The listings also cover the availability of "in-system emulators." These units are usually black boxes that look to the system like a real time IC device. But by using them the designer can modify the program and can effectively gain access to what would be interior portions of the integrated circuit to test, analyze, and debug the microprocessor while it is connected to the system.

MICROPROCESSOR–System Components

This section presents the major microprocessor system devices organized into system groups, ie F8, 6800, 8080, etc. It includes those RAM's, ROM's and PROM's which are unique to a system. It omits most general purpose memories as they are listed in the Memory section. Similarly, buffers, line drivers, transceivers, UART's, etc. are covered briefly here as they are presented in depth in the Digital and Interface sections.

Bidirectional Bus Transceiver			
	DP8304	**National**	**(501)**
Octal Bus Transceiver			
	IDM8208	National	
Interface Latch Elements (ILE)			
	DP8301	National	
System Timing Element (STE)			
	DP8302	**National**	**(496)**
	DP8305	National	
CMOS Clock			
	MM74C04	National	
Erasable PROM (See also Memory PROM's MM5204)			
	IPC-16A/506	National	
RAM (256x4) (See also Memory RAM's, MM5269)			
	IPC-16A/504	National	
Development System			
	LCDS	**National**	**(1656)**

PPS-4, PPS-8

Function	Device	Source
CPU (for PPS 4)		
	12660	Rockwell
ROM RAM (for PPS 4)		
	A07XX	Rockwell
	A08XX	Rockwell
	A20XX	Rockwell
CPU (for PPS 4/1)		
	75XX	Rockwell
	76XX	Rockwell
	77XX	Rockwell
CPU Evaluation Circuit (for PPS 4/1)		
	6799	Rockwell
CPU (for PPS 4/2)		
	11600	Rockwell
ROM RAM (for PPS 4/2)		
	A17XX	Rockwell
CPU (for PPS 8)		
	11806	Rockwell
CPU (for PPS 8/2)		
	12806	Rockwell
ROM RAM (for PPS 8/2)		
	A21XX	Rockwell

PPS-4, PPS-8 (Cont'd)

Function	Device	Source
Bus Interface Circuit (BIC)		
	10738	Rockwell
Clock Generator (CLK) (for PPS 4, PPS 8)		
	10706	Rockwell
Direct Memory Access Controller (DMA) (for PPS 8)		
	10817	Rockwell
Display Controller (DC)		
	10814	Rockwell
Floppy Disk Controller (FDC) (for PPS 8)		
	10936	Rockwell
General Purpose Keyboard and Display Control (GPKD)		
	10788	Rockwell
General Purpose Input/Output (GPI/O)		
	10696	Rockwell
Interval Timer		
	11049	Rockwell
Keyboard/Printer Controller (KPC)		
	10815	Rockwell
Printer Controller (PC)		
	10789	Rockwell
Victor Dot Matrix Printer Controller (VPC)		
	10736	Rockwell
	15380	Rockwell
Parallel Data Controller (PDC) (for PPS 8, PPS 8/12)		
	10453	Rockwell
Serial Data Controller (SDC)		
	10930	Rockwell
Telecommunications Data Interface (includes modem)		
	10371	Rockwell
RAM (256x4) (for PPS 4, PPS 4/2)		
	10432	Rockwell
RAM (512x4) (for PPS 4, PPS 4/2)		
	10932	Rockwell
RAM (256x8) (for PPS 8, PPS 8/2)		
	10809	Rockwell
4K RAM Interface		
	10929	Rockwell
RAM (4096x1) (See also Memory RAM's)		
	1604-8	Rockwell
ROM (1024x8)		
	A05XX	Rockwell
ROM (2048x8)		
	A52XX	Rockwell
ROM (4096x8)		
	A66XX	Rockwell

SBA

Function	Device	Source
Sequential Boolean Analyzer		
	SBA	GI

SBP0400

Function	Device	Source
CPU, 4 Bit Slice		
	SBP0400AC	TI
	SBP0400AM	†TI
	SBP0401AC	TI
	SBP0401AM	†TI
4 Bit Slice Control Element		
	SN54S482	†TI

SX200

Function	Device	Source
Microcomputer		
	SX200	Essex

TLCS-12

Function	Device	Source
CPU		
	T3190	Toshiba
Input/Output Control Unit		
	T3218	Toshiba
General Purpose Input/Output Register		
	T3320	Toshiba
Memory Control Unit		
	T3216	Toshiba
Erasable PROM		
	T3181	Toshiba
RAM (128x4)		
	T3151	Toshiba

W40

Function	Device	Source
Microcontroller		
	CR1872	Western
	CR2872	Western

Z80

Note: the 6500, 6800 and 8080 peripheral circuits are compatible with the Z80 series.

Function	Device	Source	
CPU			
	MK3880	Mostek	
	μPDZ-80	**NEC Micro**	**(1850)**

WHEN THE CHIPS ARE DOWN...

THE NEW 1978 ICMASTER PAYS OFF!

The new IC MASTER is the ultimate IC source book.

It lists virtually every IC device manufactured in the United States.

The IC MASTER is the easy, sensible means of narrowing down your IC choices quickly, accurately and systematically. All information is cross-referenced and indexed for rapid problem solving and device selection. And, additionally, the MASTER is updated three times yearly by accumulative supplements.

THE FORMAT OUTLINED:

- **FIVE MASTER SELECTION GUIDES** — Over 85 companies' IC's organized by type, function, key parameters
- **OVER 1500 PAGES OF TECHNICAL INFORMATION** — Provided directly by manufacturers covering 20,000 IC's
- **ALTERNATE SOURCE DIRECTORY** — The only industry-wide, pin-for-pin version available
- **MILITARY PARTS INDEX AND CROSS REFERENCE CHART** — Identifies all IC's with JAN qualification
- **MILITARY DEVICE TESTING TABLE** — List companies that screen to Mil. Std. 883
- **MILITARY PARTS INDEX** — The first functional guide to JAN qualified parts

S6800 Microcomputer Systems

The AMI S6800

The AMI S6800 Microprocessing Family hardware includes a microprocessor, ROM and RAM memories, and data input/output circuits. These components may be assembled in a building block manner into a very simple microcomputer system or into any of progressively more complex systems, which can be used in many general or special purpose applications. The important feature of the S6800 family is that within any system all components are directly compatible in signal functions, circuit performance characteristics, and logic levels. All operate on a single +5V power supply.

It remains to the user to integrate the microcomputer into his own large system and to program it for a specific task. The task may be either simple or complex and either general in purpose or highly specialized for one application.

To facilitate system design and programming, AMI will provide a comprehensive set of reference documents, design and programming aids, a program library, and other applications support. For example, AMI will make available a comprehensive hardware and software reference manual, a S6800 program assembler, and a simulator. Such design and programming support is a continuing and expanding effort at AMI.

S6800 — 8-Bit Microprocessor

The S6800/S68A00/S68B00 is an 8-bit parallel processor with the ability to address up to 65K bytes of memory and execute instructions in two microseconds. It is manufactured using N-channel MOS technology and operates on a single +5V power supply. All inputs and outputs are TTL compatible. The MPU has six internal registers, four types of vectored interrupts and 72 basic instructions. The basic instructions can be used in different addressing modes to save instruction execution time and memory space.

Another important advantage that the S6800/S68A00/S68B00 has to offer in comparison with any other microcomputer system is input/output versatility. In any computer system, large or small, the CPU internal functions are determined by its architecture and the user usually has little opportunity or need to alter them. On the other hand, the I/O configuration is almost always determined by the user and subject to change as peripherals are added or other system alternations are introduced.

S68A10/S68B10 — 1024 Bit (128x8) Static Read/Write Memory

The S68A10 and S68B10 are static Read/Write memories designed and organized to be compatible with the S68A00 and S68B00 microprocessors. Interfacing to the S68A10 and S68B10 consists of an 8-bit bi-directional data bus, seven address lines, a single Read/Write control line, and six chip enable lines, four negative and two positive.

For ease of use, the S68A10 and S68B10 are totally static memories requiring no clocks or cell refresh. The S68A10 and S68B10 are fabricated with N-channel silicon gate depletion load technology to be fully DTL/TTL compatible with only a single +5V power supply required. The data, address and control line organization and functions of the S68A10 and S68B10 match those of the MPU.

S68A21/S68B21 — Peripheral Interface Adapter (PIA)

The S68A21/S68B21 are peripheral interface adapters that provide the univeral means of interfacing peripheral equipment to the S68A00 and S68B00 Microprocessing Units (MPU). These devices are capable of interfacing the MPU to peripheral through two 8-bit bi-directional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.

©IC MASTER 1978

The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the overall operation of the interface.

The PIA interfaces to the S68A00/S68B00 MPUs with an 8-bit bi-directional data bus, three chip select lines, two register select lines, two interrupt request lines, read/write line, enable line and reset line. These signals in conjunction with the S68A00/S68B00 VMA output permit the MPU to have complete control over the PIA. VMA may be utilized to gate the input signals to the PIA.

S6831/A/B/C — 16,384 Bit (2048x8) Read Only Memory

The S6831/A/B/C is a 16,384-bit Read Only Memory organized 2K words by 8 bits. This ROM has been designed to supply large bit storage, high performance memory for microprocessors and other demanding applications with simple interface requirements. The device will operate from a single +5V power supply and is manufactured with N-channel silicon gate depletion load technology. This device is available in all common high-density ROM pinouts.

S6834 — 4096 Bit (512x8) Erasable and Electrically Reprogrammable ROM

The S6834 is a high-speed, static, 512x8 bit, erasable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatible during both read and write modes. Packaged in a 24-pin hermetically sealed dual in-line package, the bit pattern can be erased by exposing the chip to an ultra-violet light source through the transparent lid, after which a new pattern can be written. The device has +5V and -12V power supplies and is processed using a mature P-channel process.

S68A50/S68B50 — Asynchronous Communication Interface Adapter (ACIA)

The S68A50/S68B50 Asynchronous Communication Adapter (ACIA) provides the data formatting and control to interface serial asynchronous data communications to bus organized systems such as the S68A00/S68B00 Microprocessing Units.

The S68A50/S68B50 includes select enable, read/write, interrupt and bus interface logic to allow data transfer over an 8-bit bi-directional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. Word lengths, clock division ratios and transmit control through the Request-to-Send output may be programmed. For modem operation three control lines are provided.

Basic S6800 Microcomputer System

In a basic system built with the S6800 components the S6800/S68A00/S68B00 Microprocessor is supported by over 1K bytes of memory and controls one input/output interface circuit. The 1024-byte ROM is used to store the operating program, the 128-byte RAM provides working storage for the MPU, and the Peripheral Interface Adapter (PIA) provides two independently programmable 8-bit input/output ports for communicating with two peripheral devices.

The S6800 system is bus oriented. Eight lines from the data bus and 16 more lines make up the address bus. The MPU controls the bus and all other devices — the memories and the PIA — attach to the busses and wait for instructions from the MPU to supply or receive data.

©IC MASTER 1978

The basic system is a complete microcomputer, which can be used for a large variety of applications. It is simple but versatile, because it can be easily reprogrammed by changing the ROM. The user must provide only the two-phase clock signal source, a power-up/restart circuit, and a single +5V power supply to complete the hardware.

Expanding the S6800 System

The basic system can be altered or expanded in many different ways. For example, the S68A50/S68B50 Asynchronous Communication Interface Adapter (ACIA) can be substituted for the PIA, to enable the microcomputer to interface with a telecommunications modem. Or, additional memory can be added — either RAM or ROM — to expand the processing capability of the MPU. In general, the system can be expanded in a modular manner, by adding onto the bus as many as ten devices out of the S6800 family. These can be any combination of memory or input/output interface circuits. In this manner a system of nearly any complexity and configuration can be assembled. (Systems with more than ten devices on the bus require the addition of address and data bus buffers to operate at full speed.)

By building a microcomputer from the S6800 family of devices, advantage is taken of the compatibility of the devices. They all conform to the bus discipline, all are compatible in load levels, and the entire system runs on a common system clock. In effect you eliminate most all circuit design, save for the simple clock and power-up/restart circuits. Because you are dealing with only a small number of integrated circuits, circuit layout is simple and the entire microcomputer can be located on a single circuit card.

In some special purpose applications you may need to attach your own interface devices to the bus. As a result, more circuit design will be required, but you will find the S6800 MPU easy to work with. It has features that allow it to be used in many different systems. For example, by using the Halt, Three-State Control, and Data Bus Enable lines, you can easily design a direct memory access system in which either the MPU or a peripheral device can read or write into the RAM and utilize the bus on a priority basis. You can also design a multiprocessor system in which several MPUs can be attached to the same bus and share processing assignments as well as memory space.

S6800 Input/Output

One of the most important advantages that any S6800 system has to offer is its input/output versatility.

In a S6800 system the MPU relegates most of the I/O control to such I/O interfaces as the PIA or ACIA. Each of these circuits is programmable and can interface with peripheral devices without directly involving the MPU. For example, the MPU can preprogram a PIA to either output data to the MPU or to receive it. Thereafter, the PIA circuits assume all functions of interfacing with the peripherals and the MPU never has to look at the interface until service is required. It must service interrupts from the PIA, but never needs to wait for input data to become available or for output data to be accepted. This relieves the MPU of its I/O functions, makes it more efficient in its primary task of data processing, and significantly increases system throughput.

The I/O interfaces and memory are both located in the same address space with the S6800 system. The MPU can access any I/O device the same as a memory location — with address lines, instead of separate I/O control lines. Therefore, it can manipulate data in the I/O interface registers with the same programmed instructions as it uses for memory locations. This adds flexibility and increases system efficiency.

©IC MASTER 1978

The S6800 Instruction Set complements the above I/O addressing capability with specific instructions that can be used to access memory as well as I/O circuit registers and perform directly various manipulations on the data.

S6800 Instruction Set

The S6800 MPU has a set of 72 basic instructions. These include binary and decimal arithmetic functions as well as logical, shift, rotate, load, store, branch, interrupt, and stack manipulation functions. Most of the instructions have several variations and most can be used with several memory addressing modes. The total complex of instructions available to the programmer is actually 197.

An instruction can be from one to three bytes long, depending on the addressing mode used with the instruction. The first byte always contains the operation code, which designates the kind of operation the MPU will perform. In single byte instructions no memory address is required, because the operation is performed on one of the internal MPU registers. In multiple byte instructions the second and third byte can be the operand, or a memory address for the operand.

A noteworthy feature of the S6800 MPU is that some of the instructions can operate directly on any memory location. In other computer systems it is common that the processor fetches an operand from memory, stores it in the accumulator, then executes the operation in the ALU and finally writes the result back into the memory. The S6800 is able to accomplish the same with only a single instruction, because it operates with any external location in the same manner as with an internal register. For example, it can directly increment or decrement the contents of a memory location. Because the MPU addresses I/O devices just like a memory location, it can do the same with registers inside the PIA or ACIA. The ASL, ASR, LSR, and ROL are other examples of instructions which operate in this manner.

MPU Registers

Accumulators A and B — Two separate 8-bit accumulators that are used to hold operands and results of operations in the ALU.

Index Register — A 16-bit register used for memory address storage in Indexed Addressing operations.

Program Counter — A 16-bit register that holds the current program instruction address. Once the initial program starting address is loaded into the program counter, it is incremented under control of the MPU hardware.

Stack Pointer — A 16-bit register used for storage of the next available location in an external push-down/pop-up stack.

Condition Code Register — An 8-bit register that stores certain results of operations in the ALU. These bits are used as testable conditions for the conditional branch instructions. In addition, one bit position stores the interrupt mask bit and the two high order bits are unused.

Memory Register

External Stack — The MPU uses a push-down/pop-up stack that can be located anywhere in RAM and be of any convenient size. It is accessed with the stack pointer address and has several uses. First, it always stores the MPU register contents following an interrupt and return addresses during subroutine execution. Second, it can also be used by the programmer to store data during program execution.

©IC MASTER 1978

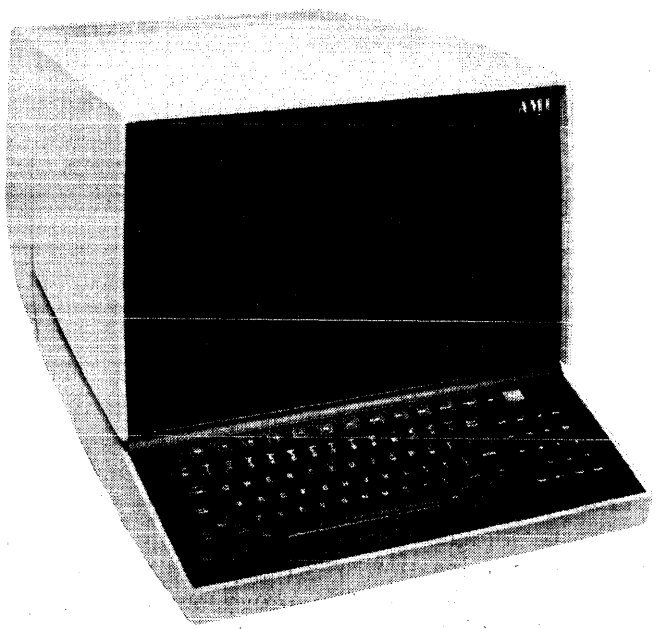
Microcomputer Development Center

What is the AMI MDC?

The AMI MDC (Microcomputer Development Center) is an intelligent stand-alone hardware debugging and software development station serving the combined needs of the engineer and programmer.

The MDC-100 is the ideal tool for design projects. The standard configuration includes an integrated terminal/computer unit and a dual floppy disk drive.

With the 16K of RAM supplied (expandable to 48K), and the remarkable display-oriented Text Editor, a source program can be created or modified very quickly. Then a Macro Assembler — one for the S6800 and another for the S2000 — can generate an object program.



The MDC's free software also support debugging with breakpoints and single steps, tracing with mnemonic disassembly, and file exchange between the floppies and a communications interface. The purchase of other software can be arranged.

A "burner" for AMI EPROMs is built into every MDC and options for some other EPROMs are available.

S2000 designers can connect the MDC to a running prototype by using the DEV-2000 Debug Module. The SES-2000 Hardware Emulator Module with its own memory can be used as a stand-alone emulator.

The MDC-140 is a general-purpose Logic Analyzer which plugs into the MDC-100. The analyzer's trace memory holds 1024 steps. All patterns are 40 channels wide — two separate event qualifiers, a data-dependent clock, and an outbound trigger.

Operation is software-controlled through the MDC's keyboard and screen, including the creation and disk storage of user-defined display formats

©IC MASTER 1978

in any mixture of binary, octal, hex, ASCII, and mnemonics.

A special keyboard design is specifically oriented toward the Development Center's function. The full ASCII keyboard with auxiliary keypad, specia. function keys and cursor controls allow rapid data entry, screen manipulation and editing.

A 16-position card cage and suitable power supply are contained in the intelligent terminal chassis so that the Development Center's options can fit inside the terminal.

A dual drive IBM-compatible floppy disk mass storage system is housed in a separate chassis. It communicates with the intelligent terminal and permits 512 kilobytes of additional on-line storage.

The AMI MDC completely eliminates the need for paper tape and offers far superior throughput over paper tape and cassette based systems. A powerful disk based operating and file management system is included to provide rapid software development. A typical edit/assembly sequence is reduced from hours in a paper tape system to minutes with the MDC.

The AMI MDC is a multi-function development center that single-handedly satisfies your requirements for:

Software Development — with a full complement of support software including FDOS-II Operating and File Management System, Text Editor, Assembler, Debugger, Trace, Telecommunications and Utilities.

Hardware Development — with remote front panel and ROM simulator functions and a modular bus-oriented PC card cage supported by general purpose breadboard cards, Extender cards, EPROM programming capability and MDC self-testing firmware.

Prototype Checkout — with the advantages of a real-time test environment, rapid test program retrieval, single/multiple step execution and hardware and software breakpoints.

The AMI Development System Concept

- Multifunctional, modular and expandable to serve not just some, but all system development needs; with simple, problem-free expandability.

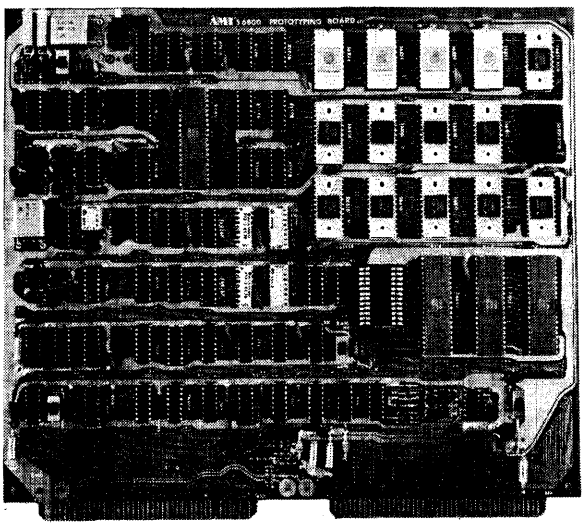
- Ready-to-use, easy-to-use. Plug in and go. Simple, easy to learn means error-free operation.

- Rapid, but quiet terminal response. No long waiting for responses to operator actions. No loud pounding of print hammers to deafen and distract the operator. A fast CRT.

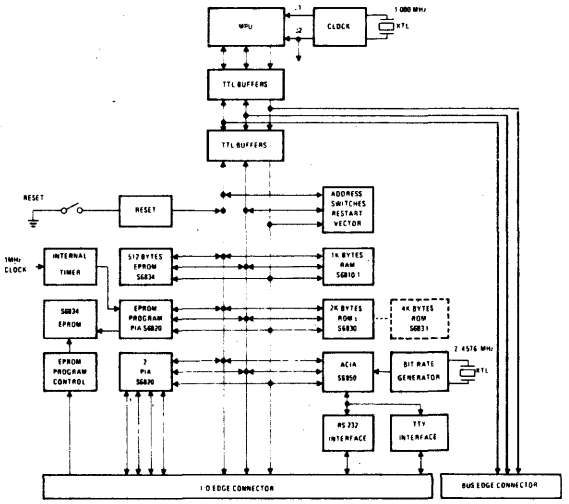
- Mass storage with disk-based operating system to end the problems of running out of memory, loading programs, and storing files. A removable storage media with full operating system support.

- Immediate access to stored programs with file management support to move quickly from one development phase to another. To draw instantly from a pool of development support software. A program library of development aids at your fingertips.

- Complete software development support to include everything necessary for the effective generation of microcomputer based software, beginning with a Disk Operating System and including text editor, assembler, debugger, trace and more.



- Complete hardware development support to solve prototype development and test problems. A bus-oriented card cage, common plug-in modules, wire wrap module, extender card, EPROM programmer and complete control-panel-type functions such as single step, stop-on-address, display, alter, and more.



The AMI Floppy Disk drive is designed to be interchangeable with an IBM 3540 or 3740 system. The recording mode is Frequency Modulation (double frequency recording) to assure high reliability. The AMI FDOS-II Floppy Disk Operating and File Management System work in conjunction with the MDC to provide unique features designed for direct use with microcomputers and microprocessors.

ADVANCED PRODUCT DESCRIPTION

77680 BLOCK DIAGRAM

FEATURES

- 2K Bytes ROM (Expandable to 4K Bytes)
- 512 Bytes EPROM (Expandable to 2K Bytes)
- 1K Bytes RAM
- EPROM Programming for S6834
- 3 PIA's = 58 I/O lines
- TTY Current Loop or RS232 Interface
- TTY Operating System Program
- ROM Subroutine Program Library
- Totally Buffered MPU Lines
- Single +5V Power Supply except when using EPROMs or RS232 Interface
- Restart Address Selection
- Selectable DMA Mode
- Interval Timer (100μs or 1 ms)
- Tiny Basic

FUNCTIONAL DESCRIPTION

The EVK 200 Prototyping Board is a kit for a single PCB, hardware/software prototyping system. It allows system development using a functionally compatible system and reduced development time. With this board, the basic 6800 family parts (S6800, S6810-1, S6820, S6831, S6834 and S6850) can be evaluated. It can also serve as a general purpose microcomputer for low volume systems to which the user can easily add I/O and memory. The 10½" x 12" card has two edge connectors, one for the MPU Bus and one for I/O.

©IC MASTER 1978

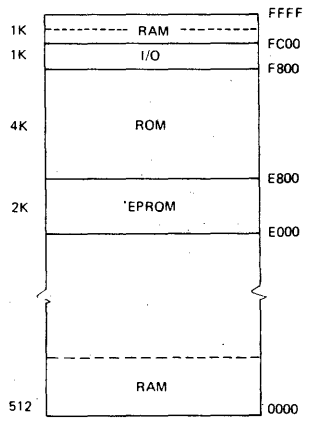
FUNCTIONAL DESCRIPTION (Cont.)

All of the S6800 microprocessor lines are available at the bus edge connector and are buffered to allow 40 mA of drive capacity for expanding the development system. The standard system clock is adjustable from 300 kHz to 1MHz by using the potentiometers on the board. An optional 1 MHz crystal may be selected to control the accuracy for those applications requiring critical timings.

An on-board interval timer gives 1 ms and 100μs timing marks for general use and for EPROM programming. Three types of DMA operation are possible using the Prototyping Board, Halt Processor, Cycle Steal or Multiplexing.

MEMORY

Memory and I/O addresses are assigned to the upper 8K bytes of the available memory space. (See memory map for address assignments.) This gives the system developer the flexibility to use the remaining 56K bytes as he wishes. All of the memory and I/O on the board may be disabled externally by an edge connector line called MEMORY DISABLE, leaving the MPU free to operate totally in an external memory.



The S6831 ROM contains the Prototype Operating Library (PROTO) and a ROM Subroutine Library $(RS)^3$. The 2K of EPROM locations may also be used for program verification. The S6831 ROM locations (2K x 8 each) will expand the ROM capacity to 4K bytes.

The RAM is assigned to the upper 1K of available memory space. The PROTO and $(RS)^3$ programs require about 256 bytes of this RAM so the rest is available for general programming. With all restart vectors automatically assigned to the upper memory addresses, restart vectoring is forced from a set of 16 switches. This allows the restart address to be vectored to any memory location.

The RAM has further been divided into two 512 byte sections such that the upper 512 bytes remain fixed in the assigned address block and the lower 512 bytes are moveable through a switch selection option. 512 bytes of RAM are relocatable to the lowest address space to take advantage of the S6800's direct addressing mode. This is only recommended if no external memory is added. When adding external memory, it is advisable to use the RAM in the upper address space and the external memory as the low addresses.

There are 512 bytes of ultra-violet erasable EPROM supplied with the board. The board has capacity for four S6834 EPROMs giving a total memory space of 2K bytes for further expansion.

ADDRESS ASSIGNMENT MEMORY MAP

1176164

*Optional Low order RAM assignment

I/O

An S6850 ACIA is used to provide a 20 mA current loop interface to a TTY or RS232 terminal. A 20 mA current loop interface and an EIA RS232 interface are both available on the board. A bit rate generator allows operation using any of the standard communication frequencies (see table) so a large variety of terminal types can be used.

Three S6820 PIAs allow up to 58 I/O lines, giving flexibility in I/O through the parallel interfaces.

TABLE

Communication Frequencies

50	baud	300	baud	19.2K baud
75	baud	600	baud

200	baud	4800	baud	
		9600	baud	

©IC MASTER 1978

EPROM PROGRAMMING

Unique to the AMI 6800 Prototyping Board is the ability to program S6834 EPROMs (512 x 8) on the board. The programming software can program an EPROM from any memory location, RAM, ROM or EPROM. It can verify a word and, if desired, change a single bit in the EPROM, provided that the change is from LOW to HIGH.

SOFTWARE

The Prototyping Board Software is comprised of a TTY Operating Program (PROTO) and is supported by a ROM Subroutine Library $(RS)^3$. The PROTO program operates on the following commands:

L	Load Memory from TTY paper tape
P	Punch a Memory location to TTY paper tape
S	Set Memory to a given value
D	Display the contents of a memory location
G	Go to a specific address and begin program execution
R	Print contents of MPU registers on the TTY
B	Burn (program) an EPROM from Memory location indicated
V	Verify the contents of an EPROM with a specified memory location
I	Input Program EPROM to RAM
M	Move a specific block of memory to a designated location
E	End of Transmission (EOT)

The commands will operate on a single character op code plus address parameters from the TTY keyboard.

The ROM Subroutine Library $(RS)^3$ operates on a single SWI (3F) command and a second byte of offset giving the S6800 an additional set of two-byte instructions. Specific subroutines (offsets) are as follows.

SUBROUTINE	MNEMONIC	FUNCTION
0	PUSHALL	All registers are pushed on to user stack
1	POPALL	All registers on user stack are loaded into MPU
2	TXAB	Contents of Index Register are transferred to A & B Accumulators
3	TABX	Contents of A & B Accumulators are transferred to Index Register
4	XABX	Contents of A & B Accumulators are exchanged with contents of Index Register
5	PUSX	Contents of Index Register are pushed onto user stack
6	PULX	Index Register is loaded with contents of user stack
7	ADDXAB	Contents of Index Register are added to contents of A & B Accumulators. Sum is in A & B Accumulators.
8	ADDABX	Contents of A & B Accumulators are added to contents of Index Register. Sum is in Index Register
9	ADDAX	Contents of Accumulator A are added to contents of Index Register. Sum is in Index Register

©IC MASTER 1978

SUBROUTINE	MNEMONIC	FUNCTION
A	ADDBX	Contents of Accumulator A are added to contents of Index Register. Sum is in Index Register
B	SUBXAB	Contents of Index Register are subtracted from contents of A & B Accumulators. Remainder is in Accumulators A & B
C	SUBABX	Contents of Accumulators are subtracted from contents of Index Register. Remainder is in Index Register
D	SUBAX	Contents of Accumulator A are subtracted from contents of Index Register. Remainder is in Index Register.
E	SUBBX	Contents of Accumulator B are subtracted from contents of Index Register. Remainder is in Index Register
F	P2HEX	Two Hexidecimal Characters (one MPU byte) are printed on the TTY
10	P4HEX	Four Hexidecimal Characters (two MPU bytes) are printed on the TTY
11	PRINTA	ASCII Character designated is printed on TTY
12	PMESS	Message designated is printed on TTY
13	VALAN	Character (byte) is checked to see if it is a valid alpha/numeric character
14	INPUTA	ASCII Character at TTY is input to MPU
15	CONHB	ASCII Character string is scanned looking for a valid Hexidecimal number. Binary equivalent is returned in Accumulators A & B
16	INDEX	Contents of Accumulator A are multiplied with the contents of Accumulator B and the product is added to the contents of the Index Register
17	MUL8	Contents of Accumulator A are multiplied with the contents of Accumulator B. Product remains in both Accumulators

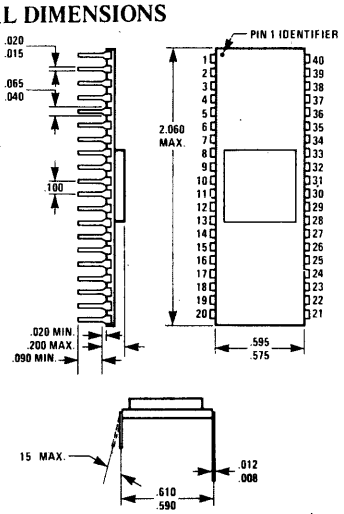
8-Bit Microprocessor



FEATURES

- Eight-Bit Parallel Processing
- Bi-Directional Data Bus
- Sixteen-Bit Address Bus – 65536 Bytes of Addressing
- 72 Instructions – Variable Length
- Seven Addressing Modes – Direct, Relative, Immediate, Indexed, Extended, Implied and Accumulator
- Variable Length Stack
- Vectored Restart
- 2 Microsecond Instruction Execution
- Maskable Interrupt Vector
- Separate Non-Maskable Interrupt – Internal Registers Saved in Stack
- Six Internal Registers – Two Accumulators, Index Register, Program Counter, Stack Pointer and Condition Code Register
- Direct Memory Access (DMA) and Multiple Processor Capability
- Clock Rates – S68A00 – 1.5 MHz
  S68B00 – 2.0 MHz
- Simple Bus Interface Without TTL
- Halt and Single Instruction Execution Capability

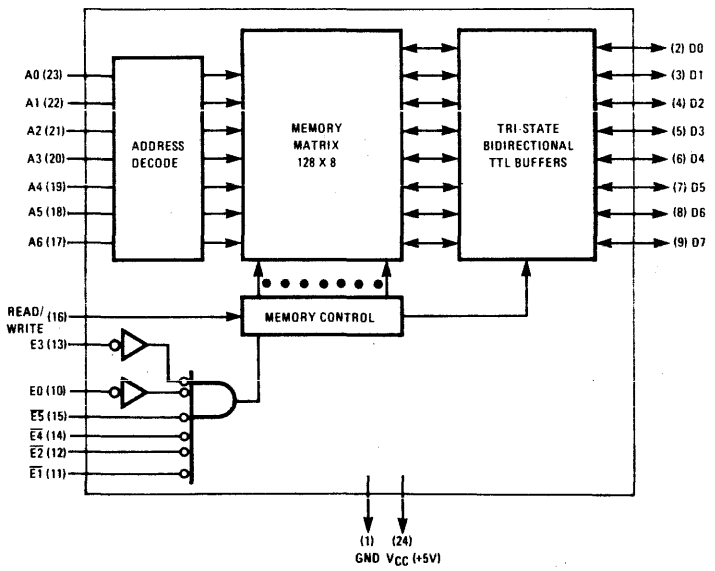
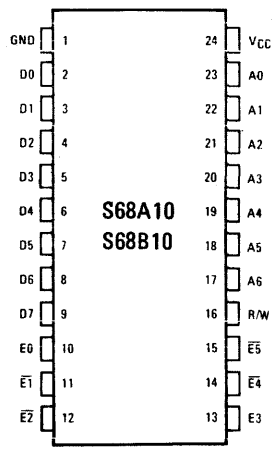
1024 Bit (128×8) Static Read/Write Memory

Features



- ☐ Organized as 128 Bytes of 8 Bits
- ☐ Static Operation
- ☐ Bidirectional Three-State Data Input/Output
- ☐ Six Chip Enable Inputs (Four Active Low, Two Active High)
- ☐ Single 5 Volt Power Supply
- ☐ TTL Compatible
- ☐ Maximum Access Time:
  —360ns for S68A10
  —250ns for S68B10

General Description



The S68A10 and S68B10 are static 128x8 Read/Write Memories designed and organized to be compatible with the S68A00 and S68B00 Microprocessors. Interfacing to the S68A10 and S68B10 consists of an 8-bit bidirectional data bus, seven address lines, a single Read/Write control line, and six chip enable lines, four negative and two positive.

For ease of use, the S68A10 and S68B10 are a totally static memory requiring no clocks or cell refresh. The S68A10 and S68B10 are fabricated with N-channel silicon gate depletion load technology to be fully DTL/TTL compatible with only a single +5 volt power supply required.

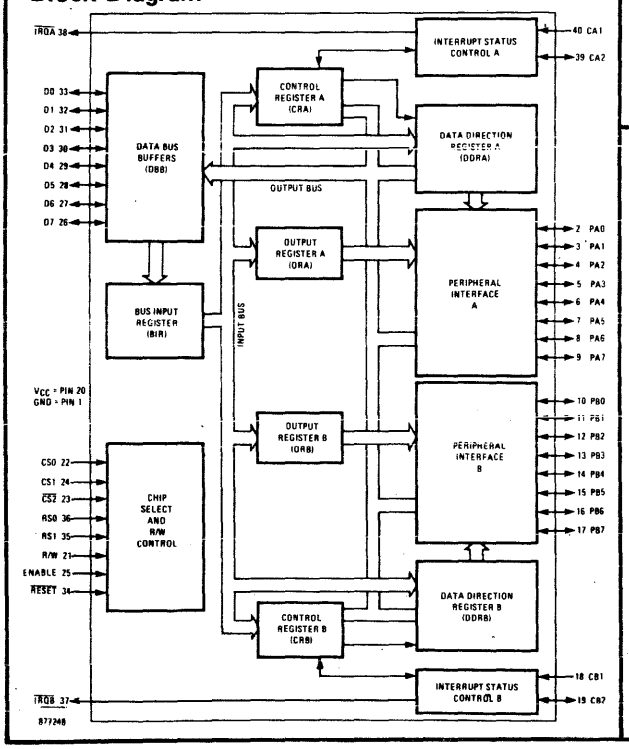
Peripheral Interface Adapter (PIA)

Features

- 8-Bit Bidirectional Data Bus for Communication with the MPU
- Two Bidirectional 8-Bit Buses for Interface to Peripherals
- Two Programmable Control Registers
- Two Programmable Data Direction Registers
- Four Individually-Controlled Interrupt Input Lines: Two Usable as Peripheral Control Outputs
- Handshake Control Logic for Input and Output Peripheral Operation
- High-Impedance Three-State and Direct Transistor Drive Peripheral Lines
- Program Controlled Interrupt and Interrupt Disable Capability
- CMOS Compatible Peripheral Lines

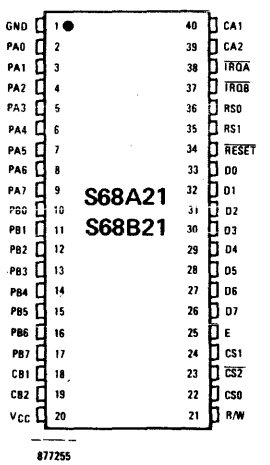
General Description

The S68A21/S68B21 are peripheral Interface Adapters that provide the universal means of interfacing peripheral equipment to the S68A00 and the S68B00 Microprocessing Units (MPU). This device is capable of interfacing the MPU to peripherals through two 8-bit bidirectional peripheral data buses and four control lines. No external logic is required for interfacing to most peripheral devices.



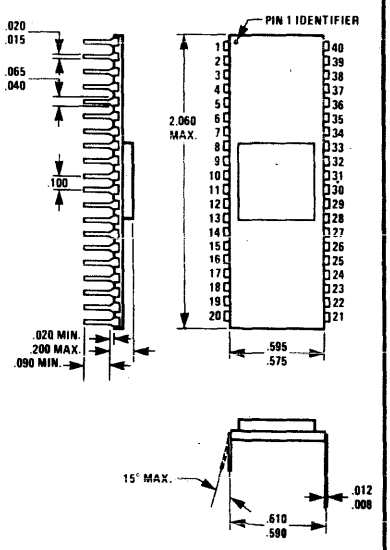
The functional configuration of the PIA is programmed by the MPU during system initialization. Each of the peripheral data lines can be programmed to act as an input or output, and each of the four control/interrupt lines may be programmed for one of several control modes. This allows a high degree of flexibility in the overall operation of the interface.

The PIA interfaces to the S68A00/S68B00 MPUs with an eight-bit bidirectional data bus, three chip select lines, two register select lines, two interrupt request lines, read/write line, enable line and reset line. These signals, in conjunction with the S68A00/S68B00 VMA output, permit the MPU to have complete control over the PIA. VMA may be utilized to gate the input signals to the PIA.



Absolute Maximum Ratings

Supply Voltage	-0.3V to +7.0V
Input Voltage	-0.3V to +7.0V
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	-55°C to +150°C



Block Diagram

Physical Dimensions

Note:
This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any votage higher than maximum rated voltages to this high impedance circuit.

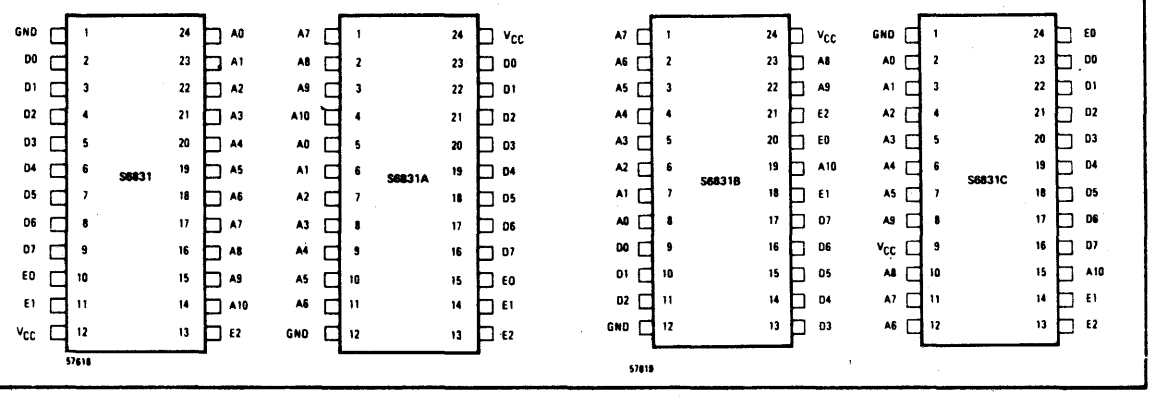
16,384 Bit (2048×8) ROM



ADVANCED PRODUCT DESCRIPTION

BLOCK DIAGRAM

PIN/PACKAGE CONFIGURATION

- Maximum Access Time = 450 ns @ C_L = 130 pF
- Low Power 150 mW avg.
- Organized as 2048-Bytes of 8 Bits
- Static Operation
- Three-State Data Output
- 3 Chip Enable Inputs (Mask Programmable)
- The S6831 is pinout similar with the S6830
- The S6831A is pinout compatible with the 2316A, 8316A
- The S6831B is pinout compatible with the Intel 2316B, MC68317
- The S6831C is pinout compatible with the EA4600
- Single 5-Volt Power Supply
- TTL Compatible Input/Output

FUNCTIONAL DESCRIPTION

The S6831/A/B/C is a 16,384 bit Read Only Memory organized 2K words x 8 bits. This ROM has been designed to supply large bit storage, high performance memory for microprocessors and other demanding applications with simple interface requirements. The device will operate from a single +5V supply and is manufactured with a N-channel silicon gate depletion load technology. This device is available in all common high density ROM pinouts.

ABSOLUTE MAXIMUM RATINGS (See Note 1)

Supply Voltage V_{CC}	- 0.5 to + 7.0V	Operating Temperature Range T_A	0 to + 70°C
Input Voltage V_{in}	- 0.5 to + 7.0V	Storage Temperature Range T_{stg}	- 55 to + 150°C

NOTE 1 Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to RECOMMENDED OPERATING CONDITIONS. Exposure to higher than recommended voltages for extended periods of time could affect device reliability.

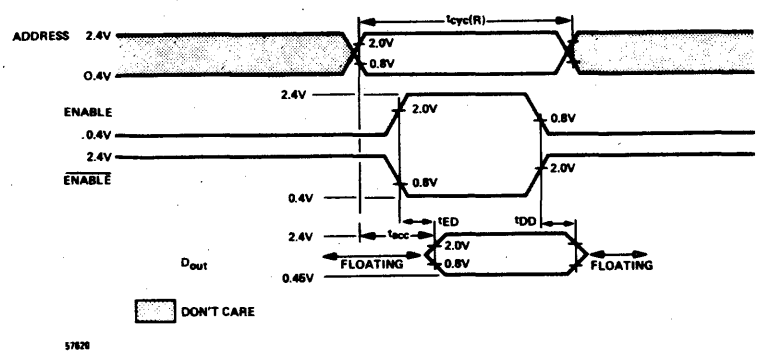
©IC MASTER 1978

DC (STATIC) CHARACTERISTICS (V_{CC} = + 5 Volt ± 5%; T_A = 0°C to + 70°C)

RECOMMENDED DC OPERATING CONDITIONS

Symbol	Parameter	Min.	Typ.	Max.	Unit	Conditions
V_{IH}	Input High Voltage (Norm. Op. Levels)	2.0	–	5.25	Vdc	
V_{IL}	Input Low Voltage (Norm. Op. Levels)	- 0.5	–	0.8	Vdc	
I_I	Input Current (V_I = 0 to 5.25 V)	–	–	2.5	μAdc	
V_{OH}	Output High Voltage (I_{OH} =-100μA)	2.4	–	–	Vdc	
V_{OL}	Output Low Voltage (I_{OL} = 2.1 mA)	–	–	0.4	Vdc	
I_{LOH}	Output Leakage Current (V_O = 2.4, $\overline{E}$ = 0.4V, E = 2.4V)	–	–	10	μAdc	
I_{LOL}	Output Leakage Current (V_O = 0.4V, $\overline{E}$ = 0.4V, E = 2.4V)	–	–	10	μAdc	
I_{CC}	Supply Current (V_{CC} = 5.25V, T_A = 0°C)	–	30		mAdc	

CAPACITANCE



Symbol	Characteristic	Min.	Typ.	Max	Unit	Conditions
C_{in}	Input Capacitance	–	–	7.5	pF	f = 1.0 MHz
C_{out}	Output Capacitance	–	–	10	pF	T_A = 25°C

FIGURE 1 – AC TEST LOAD

CUSTOM PROGRAMMING

The preferred method of pattern submission is the AMI Hex format as described below with its built-in address space mapping and error checking. This is the format produced by the AMI Assembler/Loader. The format is as follows and may be on paper tape, punched card or other media readable by AMI.

ASCII Character	Description
1	**Start of record** (S)
2	**Type of record** 0 – Header record 1 – Data record 9 – End of file record
3 – 4	**Byte Count** Since each data byte is represented as two hex characters, the byte count must be multiplied by two fo get the number of characters to the end of the record. (This includes checksum and address data.) Records may be of any length being defined in each record by the byte count.
5, 6, 7, 8	**Address Value** The memory location where this record is to be stored.
9, . . . , N	**Data** Each data byte is represented by two hex characters. Most significant character first.
N + 1, N + 2	**Checksum** The one's complement of the additive summation (without carry) of the data bytes, the address, and the byte count.

AMI will accept the input format used for the EA4600 or for the Intel 8316A or B in addition to the above format.

EXAMPLE:

```
S 1 1 3 0 0 0 0 4 9 E 9 F 1 0 3 2 0 F 0 4 9 3 1 3 9 F 7 2 0 0 0 F 5 E 0 F 0 0 1 1 D
S 9 0 3 0 0 0 0 F C

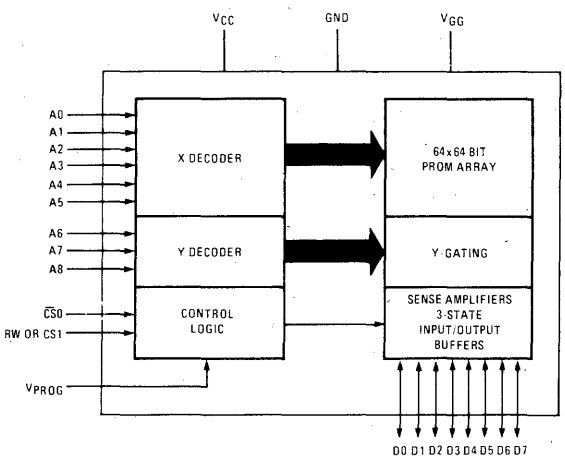
4096 Bit (512×8) Erasable and Electrically Reprogrammable ROM



FEATURES

- On-Board Programmability
- Fast Access Time – 500 ns Typ.
- Pin Configuration Similar to the S6830 1K x 8 Bit ROM
- High Speed Programming – Less than 1 Minute for all 4096 Bits
- Programmed with R/W, CS and V_{PROG} Pins
- Completely TTL Compatible – Excluding the V_{PROG} Pin during Read and Write
- Ultraviolet Light Erasable – Less than 10 Minutes
- Static Operation – No Clocks Required
- Three-State Data I/O
- Standard Power Supplies +5V and –12V
- Mature P-Chan Process

TYPICAL APPLICATIONS

- ROM Program Debugging
- Code Translation
- Microprogramming
- Look-up Tables
- Random Logic Replacement
- Programmable Waveforms
- Character Generation
- Electronic Keyboards

FUNCTIONAL DESCRIPTION

The S6834 is a high speed, static, 512 x 8 bit, eraseable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatable during both read and write modes. Packaged in a 24 pin hermetically sealed dual in-line package the bit pattern can be erased by exposing the chip to an ultra-violet light source through the transparent lid, after which a new pattern can be written.

ABSOLUTE MAXIMUM RATINGS

Voltage on any pin relative to V_{SS} except the V_{PROG} pin	+0.3V to -20V
Voltage on the V_{PROG} pin relative to V_{SS}	+0.3V to -55V
Operating Temperature	0°C to +70°C
Storage Temperature (programmed)	-55°C to +85°C
Storage Temperature (unprogrammed)	-55°C to +150°C

NOTE: This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields, however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

©IC MASTER 1978

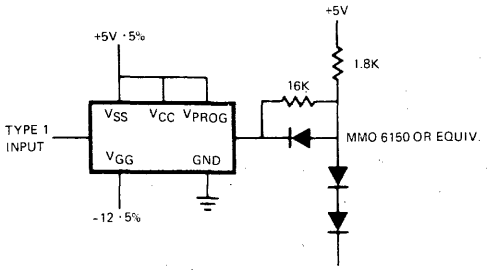
DC (STATIC) CHARACTERISTICS (V_{CC} = +5.0V ± 5%, V_{GG} = −12.0V ± 5% T_A = 0 − 70°C unless otherwise noted).

SYMBOL	CHARACTERISTIC	MIN	MAX	UNIT
V_{IL}	INPUT VOLTAGE LOW		0.8	V
V_{IH}	INPUT VOLTAGE HIGH	V_{CC} −2.25	V_{CC} to .3	V
V_{OL}	OUTPUT VOLTAGE LOW I_{OL} = 1.6 ma		0.4	V
V_{OH}	OUTPUT VOLTAGE HIGH I_{OH} = 200μA	2.4		V
I_{LI}	INPUT LEAKAGE CURRENT		10	μa
I_{LO}	OUTPUT LEAKAGE CURRENT CS = 5V		20	μa
I_{GG}	V_{GG} SUPPLY CURRENT		45	ma
I_{CC}	V_{CC} SUPPLY CURRENT		50	ma
P_D	POWER DISSIPATION		750	mw

NOTE: Program input V_{PROG} may be tied to V_{CC} during the Read.

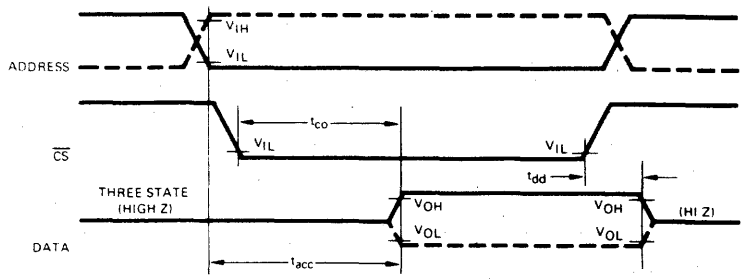
AC (DYNAMIC) CHARACTERISTICS (Loading is as shown in Figure 1 unless otherwise noted).

SYMBOL	CHARACTERISTIC	MIN	MAX (6834)	MAX (6834−1)	UNIT
T_{ACC}	ACCESS TIME		575	750	ns
T_{CO}	CHIP SELECT TO OUTPUT DELAY		300	400	ns
T_{DD}	CHIP DESELECT TO OUTPUT DELAY		250	325	ns



PROGRAM CHARACTERISTICS (R/W G_{nd}, Program pulse rise and fall time (10% to 90%) are both at 1μs max).

SYMBOL	CHARACTERISTICS	MIN	MAX	UNIT
T_{AS}	ADDRESS SET UP TIME	10		μs
T_{CSS}	CHIP SELECT SET UP TIME	10		μs
T_{DS}	DATA SET UP TIME	10		μs
T_{AH}	ADDRESS HOLD TIME	10		μs
T_{CSH}	CHIP SELECT HOLD TIME	10		μs
T_{DH}	DATA HOLD TIME	10		μs
T_{PWL}	PROGRAM PULSE WIDTH LOW	3	5	ms
T_{PWH}	PROGRAM PULSE WIDTH HIGH	500		μs
V_{PROG}*	PROGRAM AMPLITUDE	−55	−50	V
I_{PROG}	PROGRAM CURRENT		35	ma
T_{WS}	WRITE SET UP TIME	10		μs
T_{WH}	WRITE HOLD TIME	5		μs
T_{RS}	READ SET UP TIME	10		μs



*Note that in the WRITE mode the MIN value of V_{PROG} should not be exceeded and that chip select, address, and data lines may remain at TTL level, as in the READ mode.

CONTROL FUNCTION TRUTH TABLE

CS	R/W	V_{PROG}	MODE	OUTPUTS
0	0	V_{PROG}	Write	Active Data Inputs
0	1	V_{CC}	Read	Active
1	X	X	Standby	Floating

OPERATION

Initially, and after each erasure, all bits of the 6834 are in the logic "0" state (output 0 volts). Data is stored by selectively programming a logic "1" into the desired bit locations. The R/W input (pin 14) is used to select the desired mode of operation. When the R/W input is at logic "0" the chip is in the write enable mode of operation. The outputs (0_1 –0_8) are disabled (floating) with the corresponding pins becoming the data inputs ($0_1 \rightarrow D_{IN\ 1}$ etc.). The word address is selected in the same manner as in the read mode. Data to be programmed are presented 8 bits in parallel and after the address and data are set up a programming pulse (V_P –50 volts) is applied. V_{PROG} electrically writes the data into the memory array. Writing may be inhibited by deselecting the chip with the CS input at a logic "1" during the write cycle. This feature allows true "on board" programming in bus organized systems where the R/W and V_{PROG} inputs are common and the device to be programmed is selected by means of the chip select input as during read operations.

The amount of program energy required to insure memory retention may be defined as a function of the number of program pulses (N) times the program pulse width (t_{pw}) ($N \times t_{pw} \geqslant 60$ msec). This means if a 3 ms pulse is used, 20 program pulses are required, and if a 5 ms pulse is used 12 program pulses are required.

The read operation is accomplished by a logic "1" at the R/W input with the program input connected to V_{SS} potential. True data (data out = data in) is valid after the address is stable. The CS input will disable (float) the outputs when at a logic "1" to allow or tie capability.

Erasure is accomplished by exposing the array to a high intensity ultra-violet light source (such as, Ultra-Violet Products, Inc. Lamp Model S52 or UVS-54) for a period of 7 to 10 minutes. The clear optical lid should be approximately one inch away from the lamp tubes.

INTERFACE DESCRIPTION

Pin	Label	Function
(2)	D0	**Data Lines** – with the R/W line selected for Read (V_{IH}), the Data Lines (D0 through D7) are set to reflect the contents of the selected memory location. When the R/W line is set for Write (V_{IL}), the Data Lines are input to the addressed location of the 6834 when V_{PROG} is present. The Data Bus output drivers are three-state devices that remain in the high impedance (off) state when CS is in the V_{IH} state or when R/W is in the V_{IL} state.

(4)	D2	
(5)	D3	
(6)	D4	
(7)	D5	
(8)	D6	
(9)	D7	
(14)	R/W	**Read/Write** – When this input line is set to V_{IH}, the device is in the Read mode, a low (V_{IL}) signal puts it into the Write mode.
(15)	CS	**Chip Select** – This input line must be set to V_{IL} for a Read or Write operation to be performed. When it is High (V_{IH}) the output data bus is set to a high-impedance three-state condition and disables the Write operation.
(11)	V_{PROG}	**Program** – In the Write mode, a programming pulse (–50V dc) at this input causes the data at the Data Lines to be stored in the selected address. This pin should be tied to V_{CC} for normal Read operations.
(24)	A0	**Address Lines** – These lines select the 8 bit word in memory for Read or Write operation

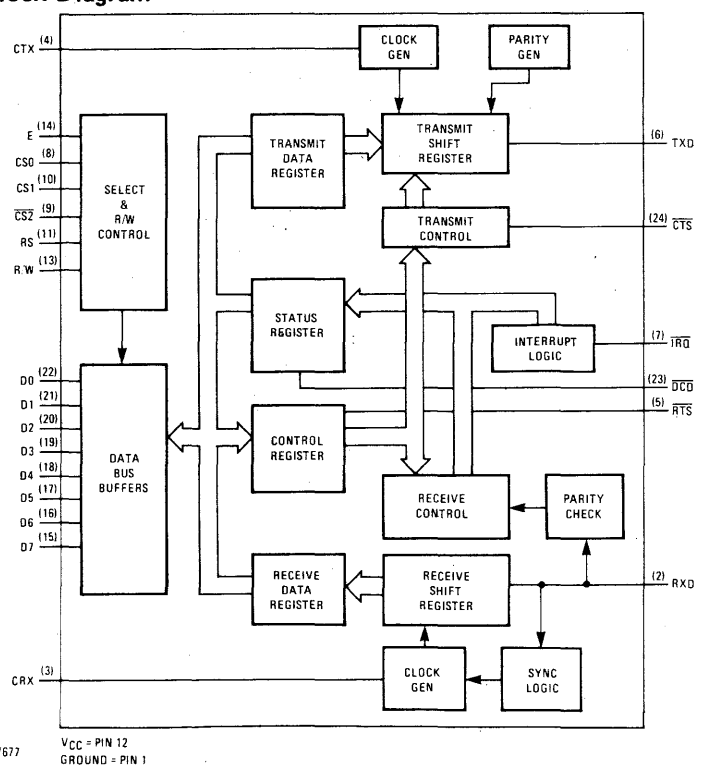
Asynchronous Communication Interface Adapter (ACIA)

Features

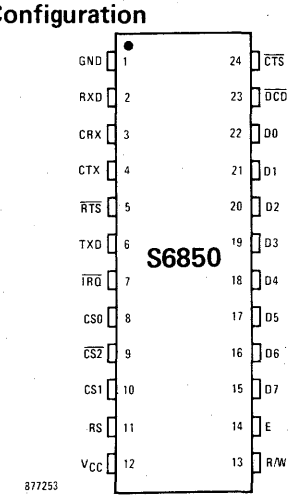
- 8 Bit Bidirectional Data Bus for Communication with MPU
- False Start Bit Deletion
- Peripheral/Modem Control Functions
- Double Buffered Receiver and Transmitter
- One or Two Stop Bit Operation
- Eight and Nine-Bit Transmission with Optional Even and Odd Parity
- Parity, Overrun and Framing Error Checking
- Programmable Control Register
- Optional ÷1, ÷16, and ÷64 Clock Modes
- Up to 500,000 bps Transmission

Absolute Maximum Ratings



Supply Voltage	−0.3V to +7.0V
Input Voltage	−0.3V to +7.0V
Operating Temperature Range	0°C to +70°C
Storage Temperature Range	−55°C to +150°C

General Description



The S68A50/S68B50 Asynchronous Communications Interface Adapter (ACIA) provides the data formatting and control to interface serial asynchronous data communications to bus organized systems such as the S68A00/S68B00 Microprocessing Units.

The S68A50/S68B50 includes select enable, read/write, interrupt and bus interface logic to allow data transfer over an eight-bit bidirectional data bus. The parallel data of the bus system is serially transmitted and received by the asynchronous data interface, with proper formatting and error checking. The functional configuration of the ACIA is programmed via the data bus during system initialization. Word lengths, clock division ratios and transmit control through the Request to Send output may be programmed. For modem operation three control lines are provided.

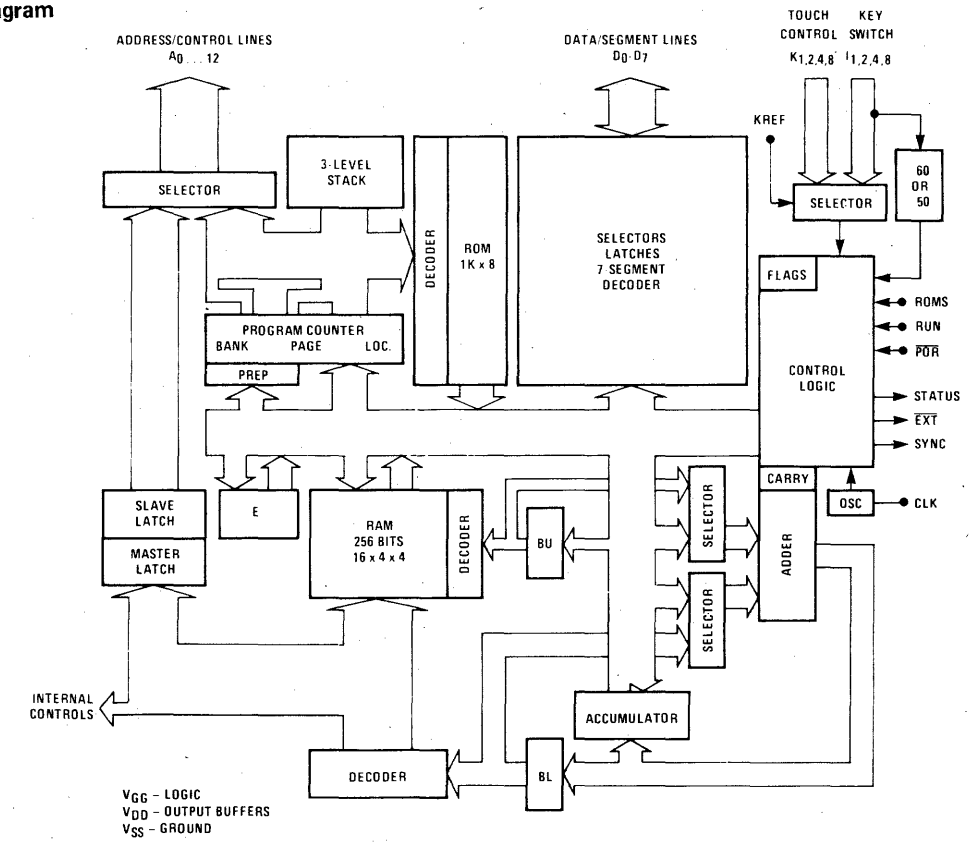
4-Bit Microcomputer



Features

- ☐ Single-Chip Architecture
- ☐ 1K x 8 ROM On Chip (Expandable to 8K x 8)
- ☐ 64x4 RAM On Chip
- ☐ 13 Outputs, 8 Inputs and 8 Bi-Directional Three-State Lines
- ☐ 7-Segment Decoder and Display Drivers On Chip:
  - S2000 — LED Drivers
  - S2000A — Vacuum Fluorescent Drivers
- ☐ TouchControl™ Capacitive Touchplate Compatibility
- ☐ Internal Timer (50Hz or 60Hz)
- ☐ Single +9V Power Supply
- ☐ Fast 4μs Execution Cycle
- ☐ 51 Instructions — All Single-Byte; 49 Single Cycle
- ☐ Three-Level Subroutine Stack
- ☐ TTL Compatible Outputs
- ☐ Reset, Test, and Step Modes

General Description

The S2000 is a fast, flexible 4-bit microcomputer which is completely self-contained with ROM, RAM, processor and input/output on one chip. Its design allows easy expansion of program storage through off-chip ROM or PROM and gives access to all internal registers and memory for debug and test.

Block Diagram

©IC MASTER 1978

Applications

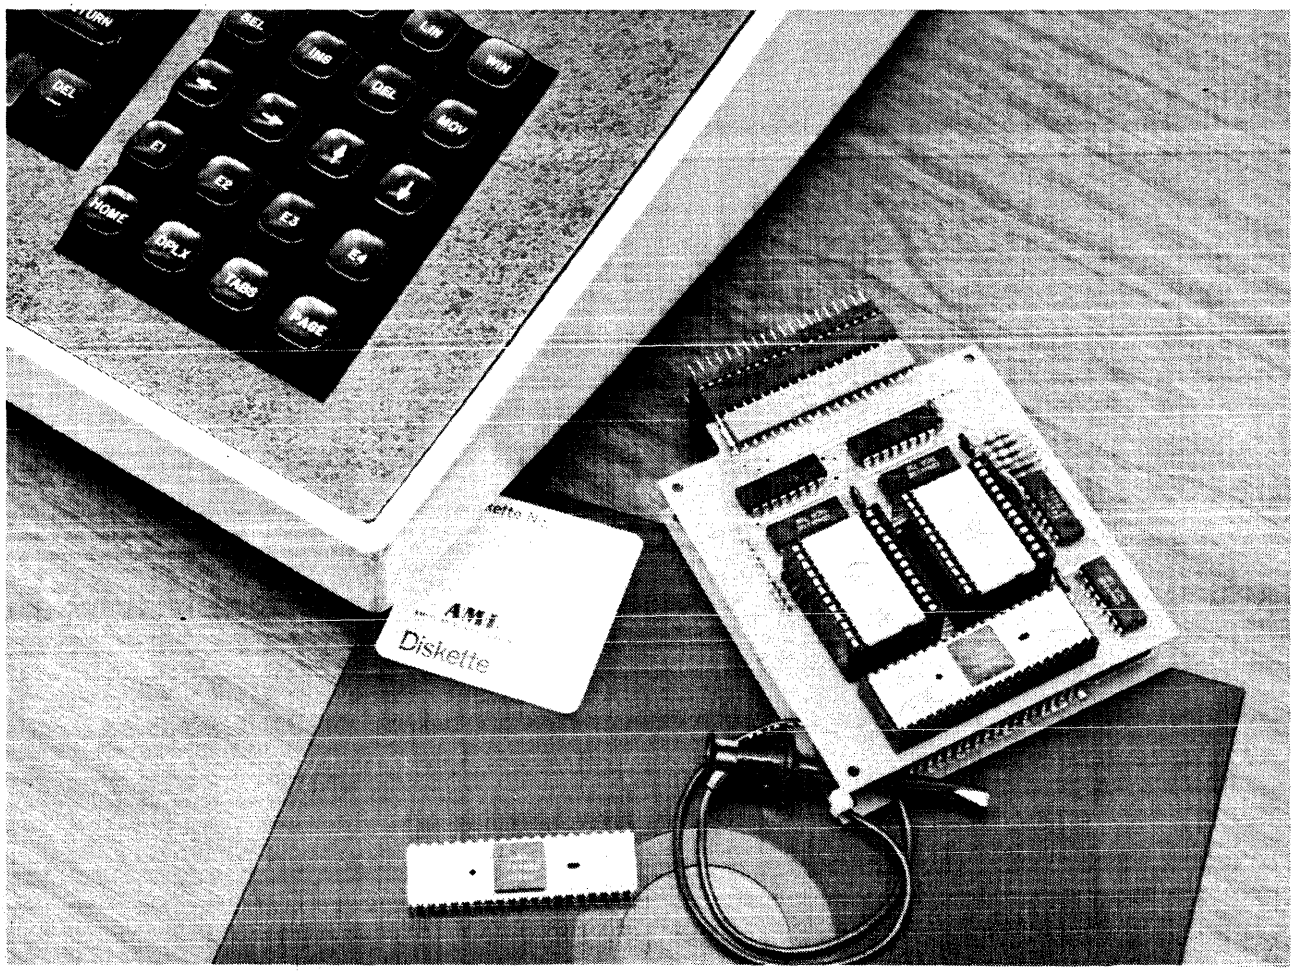
The S2000 provides the advantages of computer architecture to low-cost, minimum-parts-count display/keyboard oriented control systems. Sophisitcated I/O and ROM expandability yield a cost-effective single-chip computer that functions like more expensive multi-chip processors. It is especially suited for applications which require:

Keyboard or touch switch inputs

LED or fluorescent display

50 Hz or 60 Hz line synchronization

Motor control (phase control and/or Triac drive)



Multiple product lines where feature differentiation or model upgrading is required

S2000 Support

Complete development support is available in the forms of the MDC (Microcomputer Development Center), the DEV-2000 Debugger, the SES-2000 Emulator, the MDC-140 Logic Analyzer, TES-2000 Tester, software packages, applications engineers, and seminars.

Microcomputer Development Center

The MDC provides easy display-oriented text editing, macro assembly, software simulation, and EPROM burning.

©IC MASTER 1978

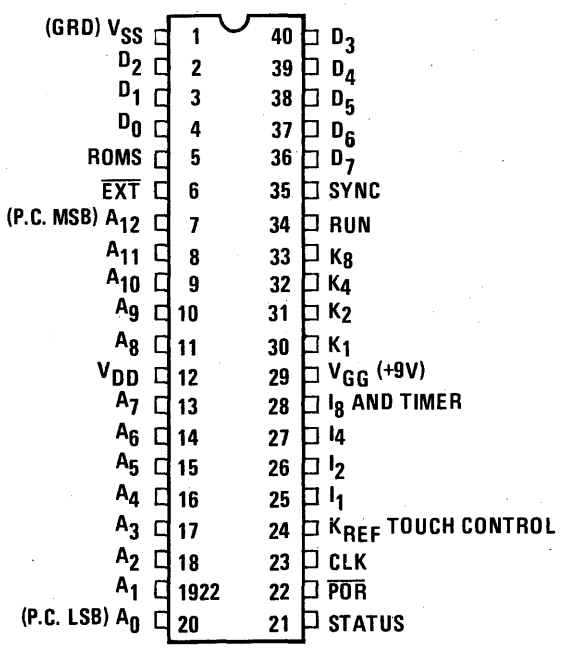
DEV-2000

The DEV-2000 Development & Debug Module links the user's prototype to the MDC. It gives quick-turn-around, on-line debug of hardware and software, including trace, step, and macro capabilities.

SES-2000

The SES-2000 is a hardware emulator which enables the user to debug prototype systems which use the S2000. The emulator uses conventional S6834 EPROMs to offer real time execution at a low cost.

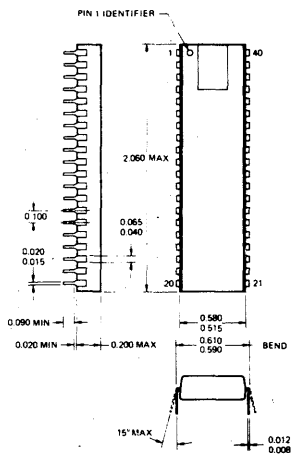
The SES-2000 emulator module measures approximately 3½" x 4½" x 1¼" and plugs into an S2000 40-pin DIP socket.



MDC-140 Logic Analyzer

This advanced Logic Analyzer provides a user-programmable MDC display of 1024 significant events appearing at its 40-channel input. Features include data-dependent clocking and oscilloscope trigger output, prewritten formats, four clock sources and programmable delay.

TES-2000



The TES-2000 is a dedicated S2000 tester which allows functional go/no-go comparison of CPU and ROM.

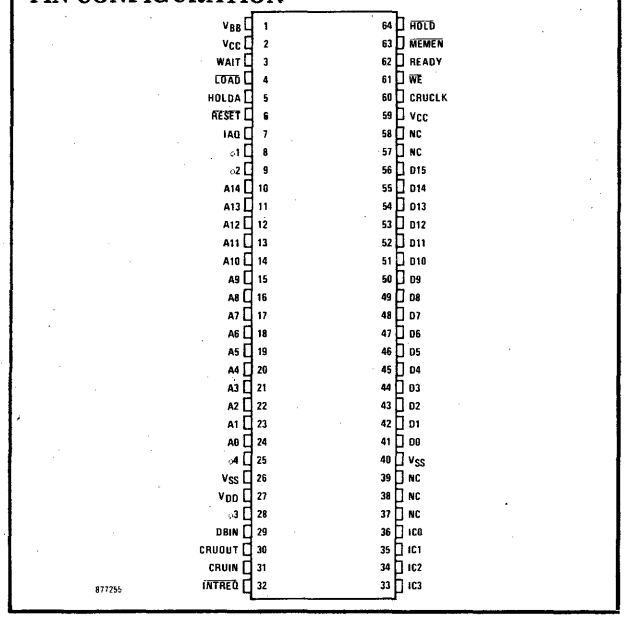
16-Bit Single Chip Microprocessor



FEATURES

- 16-Bit Instruction Word
- 8 and 16-Bit Data Format
- Bi-directional Parallel 16-Bit Data Bus
- Parallel 15-Bit Address Bus Directly Addresses 32K Words or 64K Bytes
- Advanced Memory-to-Memory Architecture that Places Multiple Register Files in Memory
- 69 Instructions, Including Multiply and Divide
- Complete Software Compatibility with the TI9900 Minicomputer Family
- 7 Addressing Modes, 16 Prioritized Interrupts, 16 General Purpose Registers per File
- Direct Memory Access
- Easy Interface with Slow Memories
- TTL Compatible
- Standard Supply Voltages (+12V, +5V, -5V)

BLOCK DIAGRAM

PIN CONFIGURATION

The S9900 microprocessor is a single-chip 16-bit central processing unit produced using N-channel silicon gate MOS technology. The instruction set of the S9900 includes the capabilities offered by full minicomputers. The unique memory-to-memory architecture features multiple register files, resident in memory, which allow faster response to interrupts and increased programming flexibility. The separate bus structure simplifies the system design effort. AMI provides a compatible set of MOS memory and logic function circuits to be used with an S9900 system. The system is fully supported by software and a complete prototyping system.

S9900 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
			ADDRESS BUS
A_0 (MSB)	24	OUT	A_0 through A_{14} comprise the address bus. This 3-state bus provides the memory-address vector to the external-memory system when MEMEN is active and I/O-bit addresses and external-instruction addresses to the I/O system when MEMEN is inactive. The address bus assumes the high-impedance state when HOLDA is active.
A_1	23	OUT	
A_2	22	OUT	
A_3	21	OUT	
A_4	20	OUT	
A_5	19	OUT	
A_6	18	OUT	
A_7	17	OUT	
A_8	16	OUT	
A_9	15	OUT

D_{13}	54	I/O	
D_{14}	55	I/O	
D_{15} (LSB)	56	I/O	

SIGNATURE	PIN	I/O	DESCRIPTION
			POWER SUPPLIES
V_{BB}	1		Supply voltage (-5V NOM)
V_{CC}	2,59		Supply voltage (5V NOM) Pins 2 and 59 must be connected in parallel.
V_{DD}	27		Supply voltage (12V NOM)
V_{SS}	26,40		Ground reference. Pins 26 and 40 must be connected in parallel.
			CLOCKS
$\phi 1$	8	IN	Phase-1 clock
$\phi 2$	9	IN	Phase-2 clock
$\phi 3$	28	IN	Phase-3 clock
$\phi 4$	25	IN	Phase-4 clock

©IC MASTER 1978

SIGNATURE	PIN	I/O	DESCRIPTION
			BUS CONTROL
DBIN	29	OUT	Data bus in. When active (high), DBIN indicates that the S9900 has disabled its output buffers to allow the memory to place memory-read data on the data bus during $\overline{\text{MEMEN}}$. DBIN remains low in all other cases except when HOLDA is active.
$\overline{\text{MEMEN}}$	63	OUT	Memory enable. When active (low), $\overline{\text{MEMEN}}$ indicates that the address bus contains a memory address.
$\overline{\text{WE}}$	61	OUT	Write enable. When active (low), $\overline{\text{WE}}$ indicates that memory write data is available from the S9900 to be written into memory.
CRUCLK	60	OUT	CRU clock. When active (high), CRUCLK indicates that external interface logic should sample the output data on CRUOUT or should decode external instructions on A_0 through A_2.
CRUIN	31	IN	CRU data in. CRUIN, normally driven by 3-state or open-collector devices, receives input data from external interface logic. When the processor executes a STCR or TB instruction, it samples CRUIN for the level of the CRU input bit specified by the address bus (A_3 through A_{14}).
CRUOUT	30	OUT	CRU data out. Serial I/O data appears on the CRUOUT line when an LDCR, SBZ, or SBO instruction is executed. The data on CRUOUT should be sampled by external I/O interface logic when CRUCLK goes active (high).
			INTERRUPT CONTROL
$\overline{\text{INTREQ}}$	32	IN	Interrupt request. When active (low), $\overline{\text{INTREQ}}$ indicates that an external interrupt is requested. If $\overline{\text{INTREQ}}$ is active, the processor loads the data on the interrupt-code-input lines IC_0 through IC_3 into the internal interrupt-code-storage register. The code is compared to the internal mask bits of the status register. If equal or higher priority than the enabled interrupt level (interrupt code equal or less than status register bits 12 through 15) the S9900 interrupt sequence is initiated. If the comparison fails, the processor ignores the request. $\overline{\text{INTREQ}}$ should remain active and the processor will continue to sample IC_0 through IC_3 until the program enables a sufficiently low priority to accept the request interrupt.
IC_0 (MSB) IC_1 IC_2 IC_3 (LSB)	36 35 34 33	IN IN IN IN	Interrupt codes. IC_0 is the MSB of the interrupt code, which is sampled when $\overline{\text{INTREQ}}$ is active. When IC_0 through IC_3 are LLLH, the highest external-priority interrupt is being requested and when HHHH, the lowest priority interrupt is being requested.
			MEMORY CONTROL
$\overline{\text{HOLD}}$	64	IN	Hold. When active (low), $\overline{\text{HOLD}}$ indicates to the processor that an external controller (e.g., DMA device) desires to utilize the address and data buses to transfer data to or from memory. The S9900 enters the hold state following a hold signal when it has completed its present memory cycle.* The processor then places the address and data buses in the high-impedance state (along with $\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) and responds with a hold-acknowledge signal (HOLDA). When $\overline{\text{HOLD}}$ is removed, the processor returns to normal operation.
HOLDA	5	OUT	Hold acknowledge. When active (high), HOLDA indicates that the processor is in the hold state and the address and data buses and memory control outputs ($\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) are in the high-impedance state.
READY	62	IN	Ready. When active (high), READY indicates that memory will be ready to read or write during the next clock cycle. When not-ready is indicated during a memory operation, the S9900 enters a wait state and suspends internal operation until the memory systems indicate ready.
WAIT	3	OUT	Wait. When active (high), WAIT indicates that the S9900 has entered a wait state because of a not-ready condition from memory.
			TIMING AND CONTROL
IAQ	7	OUT	Instruction acquisition. IAQ is active (high) during any memory cycle when the S9900 is acquiring an instruction. IAQ can be used to detect illegal op codes.
$\overline{\text{LOAD}}$	4	IN	Load. When active (low), $\overline{\text{LOAD}}$ causes the S9900 to execute a nonmaskable interrupt with memory address $FFFC_{16}$ containing the trap vector (WP and PC). The load sequence begins after the instruction being executed is completed. $\overline{\text{LOAD}}$ will also terminate an idle state. If $\overline{\text{LOAD}}$ is active during the time $\overline{\text{RESET}}$ is released, then the $\overline{\text{LOAD}}$ trap will occur after the $\overline{\text{RESET}}$ function is completed. $\overline{\text{LOAD}}$ should remain active for one instruction period. IAQ can be used to determine instruction boundaries. This signal can be used to implement cold-start ROM loaders. Additionally, front-panel routines can be implemented using CRU bits as front-panel interface signals and software-control routines to control the panel operations.
$\overline{\text{RESET}}$	6	IN	Reset. When active (low), $\overline{\text{RESET}}$ causes the processor to be reset and inhibits $\overline{\text{WE}}$ and CRUCLK. When $\overline{\text{RESET}}$ is released, the S9900 then initiates a level-zero interrupt sequence that acquires WP and PC from locations 0000 and 0002, sets all status register bits to zero, and starts execution. $\overline{\text{RESET}}$ will also terminate an idle state. $\overline{\text{RESET}}$ must be held active for a minimum of three clock cycles.

* If the cycle following the present memory cycle is also a memory cycle, it, too, is completed before the S9900 enters the hold state. The maximum number of consecutive memory cycles is three.

©IC MASTER 1978

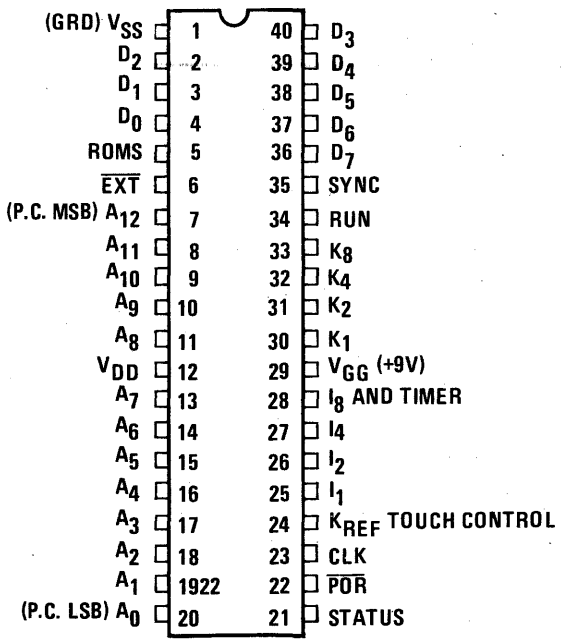
DEV-2000

The DEV-2000 Development & Debug Module links the user's prototype to the MDC. It gives quick-turn-around, on-line debug of hardware and software, including trace, step, and macro capabilities.

SES-2000

The SES-2000 is a hardware emulator which enables the user to debug prototype systems which use the S2000. The emulator uses conventional S6834 EPROMs to offer real time execution at a low cost.

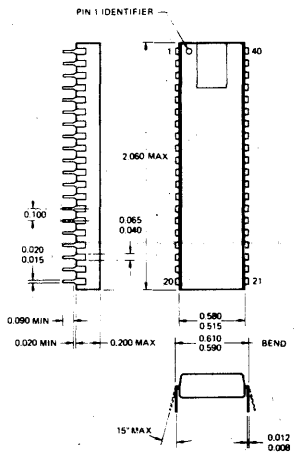
The SES-2000 emulator module measures approximately 3½" x 4½" x 1¼" and plugs into an S2000 40-pin DIP socket.



MDC-140 Logic Analyzer

This advanced Logic Analyzer provides a user-programmable MDC display of 1024 significant events appearing at its 40-channel input. Features include data-dependent clocking and oscilloscope trigger output, prewritten formats, four clock sources and programmable delay.

TES-2000



The TES-2000 is a dedicated S2000 tester which allows functional go/no-go comparison of CPU and ROM.

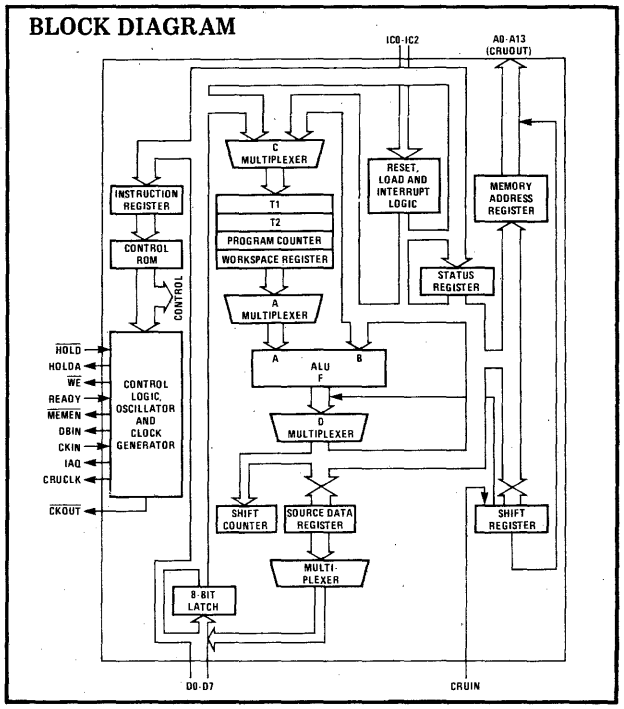
16-Bit Single Chip Microprocessor



FEATURES

- 16-Bit Instruction Word
- 8 and 16-Bit Data Format
- Bi-directional Parallel 16-Bit Data Bus
- Parallel 15-Bit Address Bus Directly Addresses 32K Words or 64K Bytes
- Advanced Memory-to-Memory Architecture that Places Multiple Register Files in Memory
- 69 Instructions, Including Multiply and Divide
- Complete Software Compatibility with the TI9900 Minicomputer Family
- 7 Addressing Modes, 16 Prioritized Interrupts, 16 General Purpose Registers per File
- Direct Memory Access
- Easy Interface with Slow Memories
- TTL Compatible
- Standard Supply Voltages (+12V, +5V, -5V)

PIN CONFIGURATION

BLOCK DIAGRAM

The S9900 microprocessor is a single-chip 16-bit central processing unit produced using N-channel silicon gate MOS technology. The instruction set of the S9900 includes the capabilities offered by full minicomputers. The unique memory-to-memory architecture features multiple register files, resident in memory, which allow faster response to interrupts and increased programming flexibility. The separate bus structure simplifies the system design effort. AMI provides a compatible set of MOS memory and logic function circuits to be used with an S9900 system. The system is fully supported by software and a complete prototyping system.

S9900 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
			ADDRESS BUS
A_0 (MSB)	24	OUT	A_0 through A_{14} comprise the address bus. This 3-state bus provides the memory-address vector to the external-memory system when MEMEN is active and I/O-bit addresses and external-instruction addresses to the I/O system when MEMEN is inactive. The address bus assumes the high-impedance state when HOLDA is active.
A_1	23	OUT	
A_2	22	OUT	
A_3	21	OUT	
A_4	20	OUT	
A_5	19	OUT	
A_6	18	OUT	
A_7	17	OUT	
A_8	16	OUT	
A_9	15	OUT	
A_{10}	14	OUT	
A_{11}	13	OUT	
A_{12}	12	OUT	
A_{13}	11	OUT	
A_{14} (LSB)	10	OUT	

SIGNATURE	PIN	I/O	DESCRIPTION
			DATA BUS
D_0 (MSB)	41	I/O	D_0 through D_{15} comprise the bi-directional 3-state data bus. This bus transfers memory data to (when writing) and from (when reading) the external-memory system when MEMEN is active. The data bus assumes the high-impedance state when HOLDA is active.
D_1	42	I/O	
D_2	43	I/O	
D_3	44	I/O	
D_4	45	I/O	
D_5	46	I/O	
D_6	47	I/O

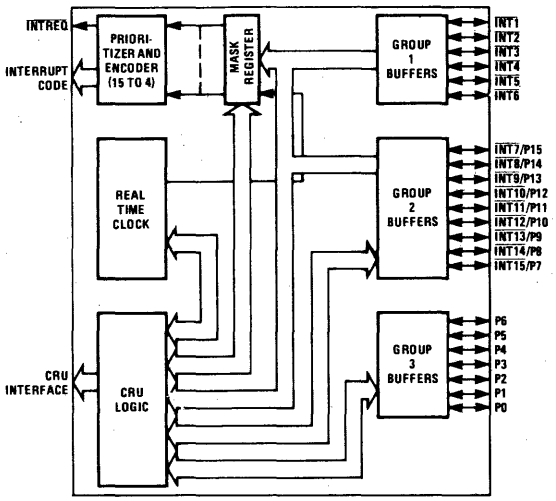
D_{13}	54	I/O	
D_{14}	55	I/O	
D_{15} (LSB)	56	I/O	

SIGNATURE	PIN	I/O	DESCRIPTION
			POWER SUPPLIES
V_{BB}	1		Supply voltage (-5V NOM)
V_{CC}	2,59		Supply voltage (5V NOM) Pins 2 and 59 must be connected in parallel.
V_{DD}	27		Supply voltage (12V NOM)
V_{SS}	26,40		Ground reference. Pins 26 and 40 must be connected in parallel.
			CLOCKS
$\phi 1$	8	IN	Phase-1 clock
$\phi 2$	9	IN	Phase-2 clock
$\phi 3$	28	IN	Phase-3 clock
$\phi 4$	25	IN	Phase-4 clock

©IC MASTER 1978



SIGNATURE	PIN	I/O	DESCRIPTION
			BUS CONTROL
DBIN	29	OUT	Data bus in. When active (high), DBIN indicates that the S9900 has disabled its output buffers to allow the memory to place memory-read data on the data bus during $\overline{\text{MEMEN}}$. DBIN remains low in all other cases except when HOLDA is active.
$\overline{\text{MEMEN}}$	63	OUT	Memory enable. When active (low), $\overline{\text{MEMEN}}$ indicates that the address bus contains a memory address.
$\overline{\text{WE}}$	61	OUT	Write enable. When active (low), $\overline{\text{WE}}$ indicates that memory write data is available from the S9900 to be written into memory.
CRUCLK	60	OUT	CRU clock. When active (high), CRUCLK indicates that external interface logic should sample the output data on CRUOUT or should decode external instructions on A_0 through A_2.
CRUIN	31	IN	CRU data in. CRUIN, normally driven by 3-state or open-collector devices, receives input data from external interface logic. When the processor executes a STCR or TB instruction, it samples CRUIN for the level of the CRU input bit specified by the address bus (A_3 through A_{14}).
CRUOUT	30	OUT	CRU data out. Serial I/O data appears on the CRUOUT line when an LDCR, SBZ, or SBO instruction is executed. The data on CRUOUT should be sampled by external I/O interface logic when CRUCLK goes active (high).
			INTERRUPT CONTROL
$\overline{\text{INTREQ}}$	32	IN	Interrupt request. When active (low), $\overline{\text{INTREQ}}$ indicates that an external interrupt is requested. If $\overline{\text{INTREQ}}$ is active, the processor loads the data on the interrupt-code-input lines IC_0 through IC_3 into the internal interrupt-code-storage register. The code is compared to the internal mask bits of the status register. If equal or higher priority than the enabled interrupt level (interrupt code equal or less than status register bits 12 through 15) the S9900 interrupt sequence is initiated. If the comparison fails, the processor ignores the request. $\overline{\text{INTREQ}}$ should remain active and the processor will continue to sample IC_0 through IC_3 until the program enables a sufficiently low priority to accept the request interrupt.
IC_0 (MSB)	36	IN	Interrupt codes. IC_0 is the MSB of the interrupt code, which is sampled when $\overline{\text{INTREQ}}$ is active. When IC_0 through IC_3 are LLLH, the highest external-priority interrupt is being requested and when HHHH, the lowest priority interrupt is being requested.
IC_1	35	IN	
IC_2	34	IN	
IC_3 (LSB)	33	IN	
			MEMORY CONTROL
$\overline{\text{HOLD}}$	64	IN	Hold. When active (low), $\overline{\text{HOLD}}$ indicates to the processor that an external controller (e.g., DMA device) desires to utilize the address and data buses to transfer data to or from memory. The S9900 enters the hold state following a hold signal when it has completed its present memory cycle.* The processor then places the address and data buses in the high-impedance state (along with $\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) and responds with a hold-acknowledge signal (HOLDA). When $\overline{\text{HOLD}}$ is removed, the processor returns to normal operation.
HOLDA	5	OUT	Hold acknowledge. When active (high), HOLDA indicates that the processor is in the hold state and the address and data buses and memory control outputs ($\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) are in the high-impedance state.
READY	62	IN	Ready. When active (high), READY indicates that memory will be ready to read or write during the next clock cycle. When not-ready is indicated during a memory operation, the S9900 enters a wait state and suspends internal operation until the memory systems indicate ready.
WAIT	3	OUT	Wait. When active (high), WAIT indicates that the S9900 has entered a wait state because of a not-ready condition from memory.
			TIMING AND CONTROL
IAQ	7	OUT	Instruction acquisition. IAQ is active (high) during any memory cycle when the S9900 is acquiring an instruction. IAQ can be used to detect illegal op codes.
$\overline{\text{LOAD}}$	4	IN	Load. When active (low), $\overline{\text{LOAD}}$ causes the S9900 to execute a nonmaskable interrupt with memory address $FFFC_{16}$ containing the trap vector (WP and PC). The load sequence begins after the instruction being executed is completed. $\overline{\text{LOAD}}$ will also terminate an idle state. If $\overline{\text{LOAD}}$ is active during the time $\overline{\text{RESET}}$ is released, then the $\overline{\text{LOAD}}$ trap will occur after the $\overline{\text{RESET}}$ function is completed. $\overline{\text{LOAD}}$ should remain active for one instruction period. IAQ can be used to determine instruction boundaries. This signal can be used to implement cold-start ROM loaders. Additionally, front-panel routines can be implemented using CRU bits as front-panel interface signals and software-control routines to control the panel operations.
$\overline{\text{RESET}}$	6	IN	Reset. When active (low), $\overline{\text{RESET}}$ causes the processor to be reset and inhibits $\overline{\text{WE}}$ and CRUCLK. When $\overline{\text{RESET}}$ is released, the S9900 then initiates a level-zero interrupt sequence that acquires WP and PC from locations 0000 and 0002, sets all status register bits to zero, and starts execution. $\overline{\text{RESET}}$ will also terminate an idle state. $\overline{\text{RESET}}$ must be held active for a minimum of three clock cycles.

* If the cycle following the present memory cycle is also a memory cycle, it, too, is completed before the S9900 enters the hold state. The maximum number of consecutive memory cycles is three.

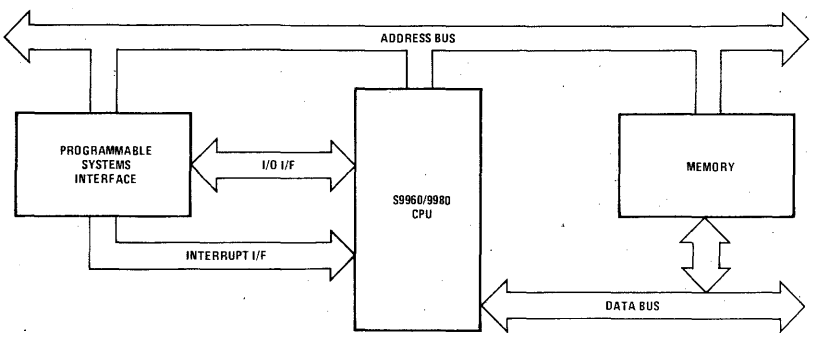
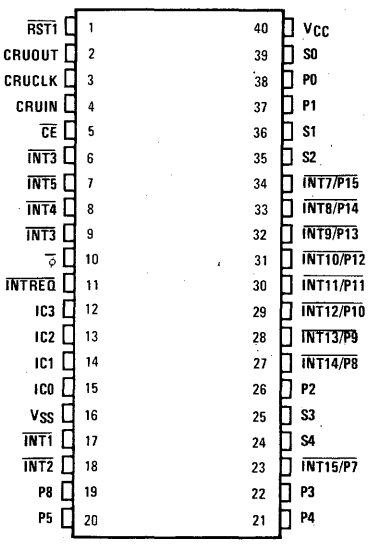
Programmable Systems Interface Circuit

BLOCK DIAGRAM



FEATURES



- N-Channel Silicon Gate Process
- S9900 Series CPU Peripheral
- Performs Interrupt and I/O Functions
  - 6 Dedicated Interrupt Input Lines
  - 7 Dedicated I/O Ports
  - 9 Ports Programmable as Interrupt or I/O
- Easily Stacked for Interrupt and I/O Expansion
- Interval and Event Timer
- Single +5V Power Supply

The S9901 Programmable Systems Interface is a multi-functioned component designed to provide low cost interrupts and I/O ports in a S9900/S9980 microprocessor system. It is fabricated with N-channel silicon gate technology and is completely TTL compatible on all inputs and outputs including the +5V power supply and single-phase clock, I/O ports, and a real-time clock. The main interface is through the Communications Register Unit as well as the interrupt control lines.

9900/9980 SYSTEM

PIN CONFIGURATION

S9901 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
$\overline{\text{INTREQ}}$	11	OUT	INTERRUPT Request. When active (low) $\overline{\text{INTREQ}}$ indicates that an enabled interrupt has been received. $\overline{\text{INTREQ}}$ will stay active until all enabled interrupt inputs are removed.
IC0 (MSB)	15	OUT	Interrupt Code lines. IC0-IC3 output the binary code corresponding to the highest priority enabled interrupt. If no enabled interrupts are active IC0-IC3 = (1, 1, 1, 1).
IC1	14	OUT	
IC2	13	OUT	
IC3 (LSB)	12	OUT	
$\overline{\text{CE}}$	5	IN	Chip Enable. When active (low) data may be transferred through the CRU interface to the CPU. $\overline{\text{CE}}$ has no effect on the interrupt control section.
S0	39	IN	Address select lines. The data bit being accessed by the CRU interface is specified by the 5-bit code appearing on S0-S4.
S1	36	IN	
S2	36	IN	
S3	25	IN	
S4	24	IN	
CRUIN	4	OUT	CRU data in (to CPU). Data specified by S0-S4 is transmitted to the CPU by CRUIN. When $\overline{\text{CE}}$ is not active CRUIN is in a high-impedance state.
CRUOUT	2	IN	CRU data out (from CPU). When $\overline{\text{CE}}$ is active, data present on the CRUOUT input will be sampled during CRUCLK and written into the command bit specified by S0-S4.
CRUCLK	3	IN	CRU Clock (from CPU). CRUCLK specifies that valid data is present on the CRUOUT line.
$\overline{\text{RST1}}$	1	IN	Power Up Reset. When active (low) $\overline{\text{RST1}}$ resets all interrupt masks to "0", disables the clock, and programs all I/O ports to inputs. $\overline{\text{RST1}}$ has a Schmitt-Trigger input to allow implementation with an RC circuit as shown in Figure 6.
V_{CC}	40		Supply Voltage. +5V nominal.
V_{SS}	16		Ground Reference.
$\overline{\phi}$	10		System clock ($\overline{\phi}3$ in S9900 system, $\overline{\text{CKOUT}}$ in S9980 system).
$\overline{\text{INT1}}$	17	IN	Group 1, interrupt inputs. When active (low) the signal is ANDed and its corresponding mask bit and if enabled sent to the interrupt control section. INT1 has highest priority.
$\overline{\text{INT2}}$	18	IN	
$\overline{\text{INT3}}$	9	IN	
$\overline{\text{INT4}}$	8	IN	
$\overline{\text{INT5}}$	7	IN	
$\overline{\text{INT6}}$	6	IN	
$\overline{\text{INT7}}$/P15	34	I/O	Group 2, programmable interrupt (active low) or I/O pins (true logic). Each pin is individually programmable as an interrupt, an input port, or an output port.
$\overline{\text{INT8}}$/P14	33	I/O	
$\overline{\text{INT9}}$/P13	32	I/O	
$\overline{\text{INT10}}$/P12	31	I/O	
$\overline{\text{INT11}}$/P11	30	I/O	
$\overline{\text{INT12}}$/P10	29	I/O	
$\overline{\text{INT13}}$/P9	28	I/O	
$\overline{\text{INT14}}$/P8	27	I/O	
$\overline{\text{INT15}}$/P7	23	I/O	
P0	38	I/O	Group 3, I/O ports (true logic). Each pin is individually programmable as an input port or an output port.
P1	37	I/O	
P2	26	I/O	
P3	22	I/O	
P4	21	I/O	
P5	20	I/O	
P6	19	I/O

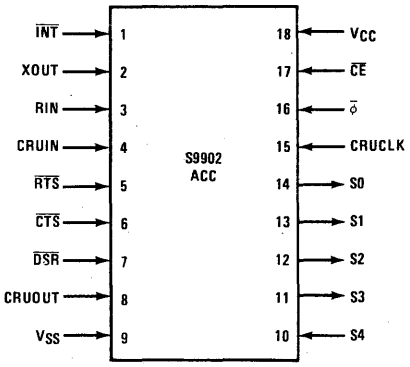
Asynchronous Communications Controller (ACC)

BLOCK DIAGRAM

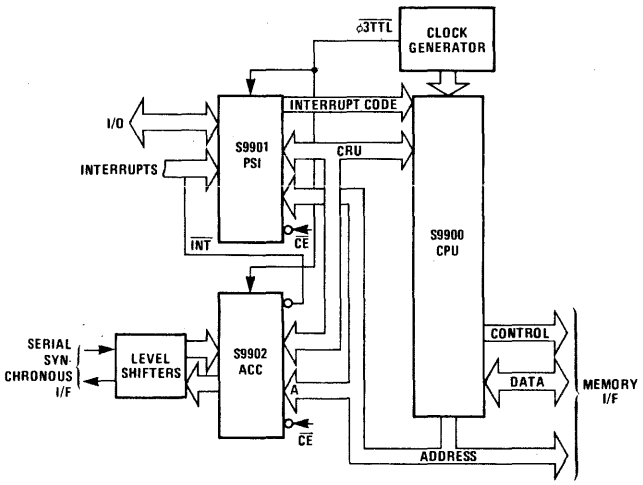
FEATURES

- 5 to 8-Bit Character Length
- 1, 1½ or 2 Stop Bits
- Even, Odd, or No Parity
- Fully Programmable Data Rate Generation
- Interval Timer with Resolution from 64 to 16,329μs
- Fully TTL Compatible, Including Single Power Supply



The S9902 Asynchronous Communication Controller (ACC) is a peripheral device for the S9900 family of microprocessors. The ACC provides an interface between the microprocessor and a serial asynchronous communication channel, performing the timing and data serialization and deserialization, thus facilitating the control of the asynchronous channel by the microprocessor.

S9902 PIN ASSIGNMENTS AND FUNCTIONS



SIGNATURE	PIN	I/O	DESCRIPTION
$\overline{INT}$	1	O	Interrupt — when active (low), the $\overline{INT}$ output indicates that at least one of the interrupt conditions has occured.
XOUT	2	O	Transmitter serial data output line — XOUT remains inactive (high) when S9902 is not transmitting.
RIN	3	I	Receiver serial data input line — RCV — must be held in the inactive (high) state when not receiving data. A transition from high to low will activate the receiver circuitry.
CRUIN	4	O	Serial data output pin from S9902 to CRUIN input pin of the CPU.
$\overline{RTS}$	5	O	Request-to-send output from S9902 to modem. This output is enabled by the CPU and remains active (low) during transmission from the S9902.
$\overline{CTS}$	6	I	Clear-to-send input from modem to S9902. When active (low), it enables the transmitter section of S9902.
$\overline{DSR}$	7	I	Data set ready input from modem to S9902. This input generates an interrupt when going On or Off.
CRUOUT	8	I	Serial data input line to S9902 from CRUOUT line of the CPU.
V_{SS}	9	I	Ground reference voltage.
S4 (LSB)	10	I	
S3	11	I	
S2	12	I	
S1	13	I	
S0	14	I	Address bus S0-S4 are the lines that are addressed by the CPU to select a particular S9902 function.
CRUCLK	15	I	CRU Clock. When active (high) S9902 from CRUOUT line of the CPU.
$\overline{\phi}$	16	I	TTL Clock.
$\overline{CE}$	17	I	Chip enable — when $\overline{CE}$ is inactive (high), the S9902 address decoding is inhibited which prevents execution of any S9902 command function. CRUIN remains at high-impedance when $\overline{CE}$ is inactive (high).
V_{CC}	18	I	Supply voltage (+5V nominal).

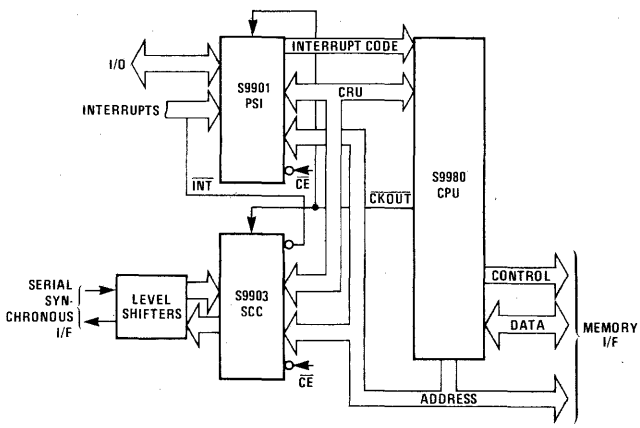
Synchronous Communications Controller

FEATURES



- Versatile CRU Interface to Synchronous and Asynchronous Serial Devices for the S99XX Series of Microprocessors
- Dynamic Character Length Selection
- Programmable Polynominal CRC Generation and Detection
- Two Programmable Sync Registers
- On-Chip Interval Timer (61μs to 16.32 ms)
- Single +5V Power Supply, 20-Pin DIP, All Inputs and Outputs TTL Compatible

The S9903 is a versatile device which provides the system designer with a wide range of capabilities in synchronous and asynchronous communications control. The S9903 operates in a multi-mode configuration that allows a broad range in the degree of active participation required in the control of sync and fill characters, timing, CRC generation and detection. Established protocols such as BI-SYNC, SDLC, and HDLC are implemented through various combinations of hardware and software.

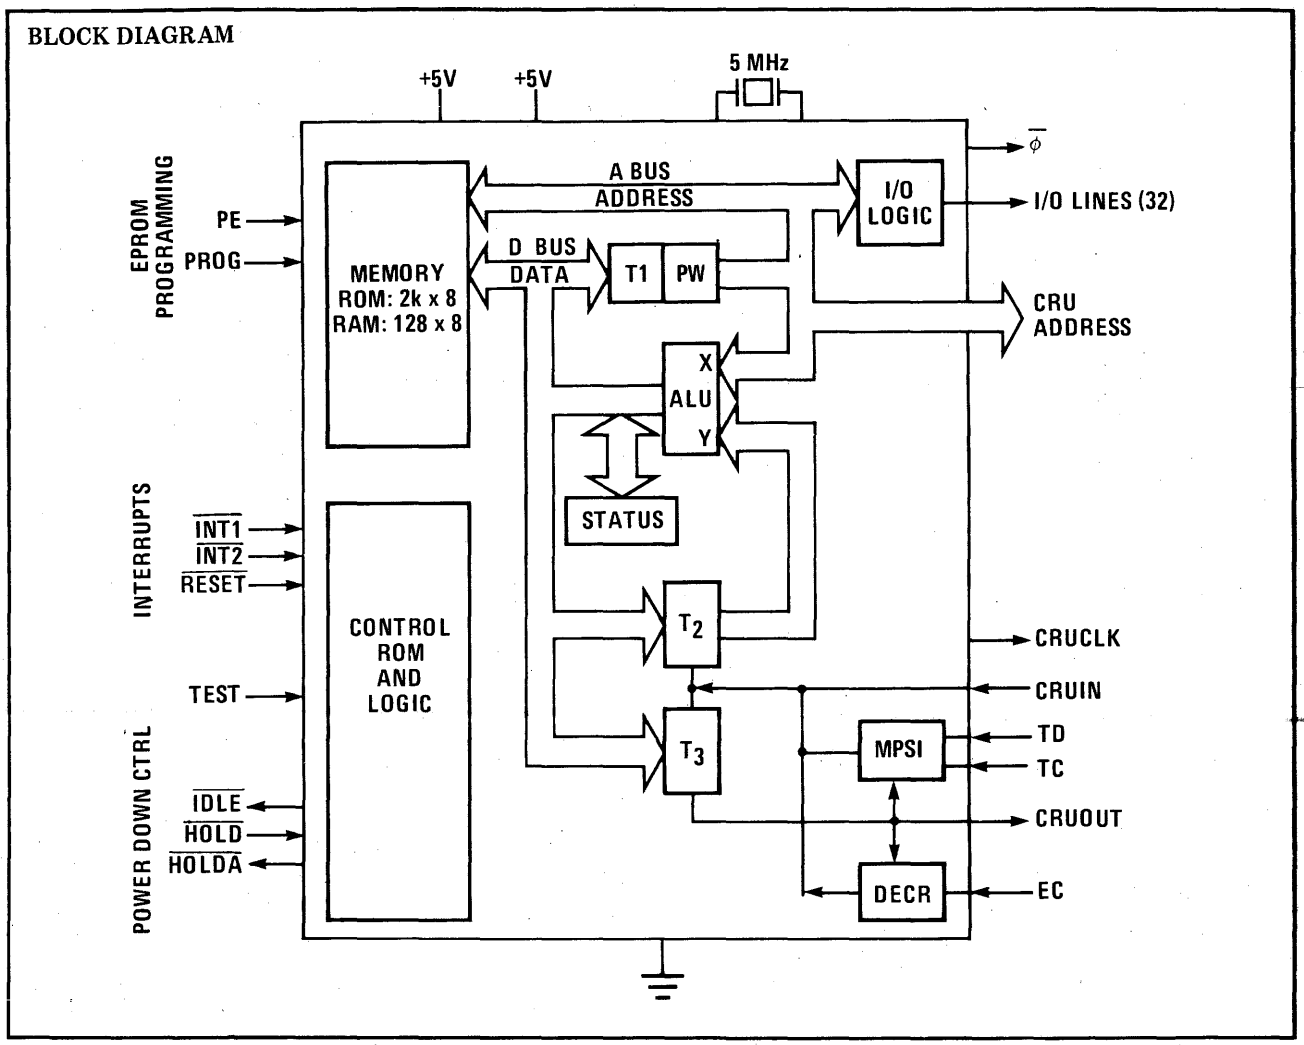
PIN CONFIGURATION



S9903 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
$\overline{INT}$	1	OUT	Interrupt — When active (low), the $\overline{INT}$ output indicates that at least one of the interrupt conditions has occurred.
XOUT	2	OUT	Transmitter serial data output line.
RIN	3	IN	Receiver serial data input line.
CRUIN	4	OUT	Serial Data Output line from S9903 to CRUIN input line of the CPU.
$\overline{RTS}$	5	OUT	Request to Send output from S9903 to modem. This output is enabled by the CPU and remains active (low) during data transmission from S9903.
$\overline{CTS}$	6	IN	Clear-to-send input from modem to S9903. When active (low), it enables the transmitter section of the S9903.
$\overline{DSR}$	7	IN	Data Set Ready input from modem to S9903. This input generates an interrupt when going On or Off.
CRUOUT	8	IN	Serial data input line to S9903 from CRUOUT line of the CPU.
V_{SS}	9	IN	Ground Reference Voltage
$\overline{SCT}$	10	IN	Transmit clock — Transmitter data is shifted out on one-to-zero transition of $\overline{SCT}$.
SCR	11	IN	Receiver clock — Receiver serial data (RIN) is sampled at zero-to-one transition of SCR.
S4(LSB)	12	IN	Address bus S0-S4 are the lines that are addressed by the CPU to select a particular S9903 function.
S3	13	IN	
S2	14	IN	
S1	15	IN	
S0(MSB)	16	IN	
CRUCLK	17	IN	CRU Clock. When active (high), S9903 samples the input data on CRUOUT line.
$\bar{\phi}$	18	IN	TTL Clock
$\overline{CE}$	19	IN	Chip Enable — When $\overline{CE}$ is inactive (high), the S9903 address decoding is inhibited. CRUIN remains at high impedance when $\overline{CE}$ is inactive (high).
V_{CC}	20	IN	Supply voltage (+5V nominal)

16-Bit Single Chip Microcomputer

BLOCK DIAGRAM

FEATURES

- 32 Bits General Purpose I/O, 256 Bits I/O Expansion
- Multiprocessor System Interface
- Single +5V Power Supply
- Power Down Mode for Low Standby Power
- 5MHz Operation
- 58 Instructions Including Multiply and Divide
- 128 Bytes RAM and 2048 Bytes ROM On Chip
- Mask Programmable and EPROM Versions
- 16 General Purpose Registers, 4 Prioritized Interrupts 16 User-Defined Program Control Flags
- Timer/Event Counter On Chip

The S9940 is a single-chip microcomputer containing a 16-bit CPU memory and extensive input/output capability. The memory consists of 128 bytes of read/write RAM and 2048 bytes of either mask programmable ROM (S9940N) or electrically reprogrammed ROM (S9940E). The S9940 is directly compatible with all members of the S9900 family of peripherals and is fully supported by both hardware and software development systems.

©IC MASTER 1978

AMI custom microcircuits are complex digital circuits designed to perform a specific function. Most could be described as "dedicated microprocessors." Because they are designed from scratch for a particular end product, custom microcircuits waste no space or capability, packing the maximum number of functions into the minimum area on the MOS/LSI chip. For volume applications, when compared with microprocessors, combinations of standard microcircuits, discrete electronic components, or electromechanical devices, custom microcircuits are often the most cost effective alternative.

No other company can match AMI's track record in developing state-of-the-art custom MOS circuits. Since 1966 AMI has been providing customers with circuits that have enhanced the marketability of their products by added features, continuously increasing reliability and reduced space requirements.

AMI not only has the experience but also the design engineering organization, and the technologically advanced production and testing facilities, to make the highest quality MOS/LSI circuits. Because AMI also manufactures standard, memory, and microprocessor products, all using a variety of advanced microcircuit process technologies, the company can be objective in helping customers determine their most cost effective approach. For example, AMI will participate in the design cycle of the custom circuit only to the extent needed by the customer. This ranges from zero to the complete design task.

With more than 1,000 custom devices designed and manufactured during the past 10 years, AMI has more experience than any other IC manufacturer in building a wide variety of custom microcircuits. The following are some of the products in which AMI custom circuits are being used: consumer, business, communications/navigation, industrial/instrumentation, and terminal/peripheral.

AMI's custom capability encompasses the entire development sequence of a product. The services which AMI provides to the customer start with five conceptual planning steps:

- System Definition
- System Design and Partitioning
- Preliminary Logic Design and Simulation
- Final Logic Design
- Chip Circuit Design

First, system definition requires the customer to have full knowledge of the system requirements for the circuit. Working with AMI's MOS/LSI application experts, the two companies form a team to develop a system which not only meets the needs, but also optimizes performance and economy.

Step two, system partitioning, follows the joint system definition. Partitioning involves the cataloguing of functions into MOS subfunctions and then into chip functions. During this step of the program the best MOS process for the application is selected. Usually, functional flow charts and timing diagrams are generated as a preliminary step in the logic design.

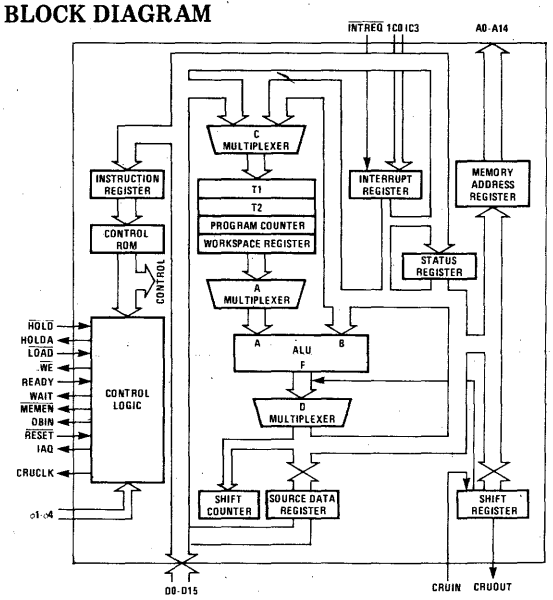
Once partitioning is accomplished, preliminary logic design and simulation can be done. The chip functions, as catalogued in step two, are translated into MOS logic diagrams and traditional breadboarding techniques are quite often used to verify these logic designs. AMI also uses proprietary computerized simulation programs for verification. These programs check the design, as well as help reduce time and cost of design verification.

Final logic design is next. First, errors discovered through breadboarding or simulation are corrected. Earlier partitioning may be refined, if the final logic design indicates a need. During the final logic design step, all system design objectives are analyzed again, MOS logic diagrams are finalized, chip sizes are estimated, and testing procedures are generated.

And then — chip circuit design. The topological chip layout is a precise science. The exact dimensions and placement of each transistor and other functions must be determined. The list of factors affecting chip design is almost endless: the use of space, the economy of functions, the versatility of functions, the power requirements, the manufacturing processes, the interconnections, the packaging, the performance of the circuit, the reliability of the design, and so on. All must be considered in the circuit layout design leading to final topological definition. Here again, AMI uses computerized circuit analysis programs to validate chip design and verify that the design meets performance objectives determined during system definition. The computerized analysis not only substantiates the logic, it is an integral part of the ongoing quality assurance program at AMI.

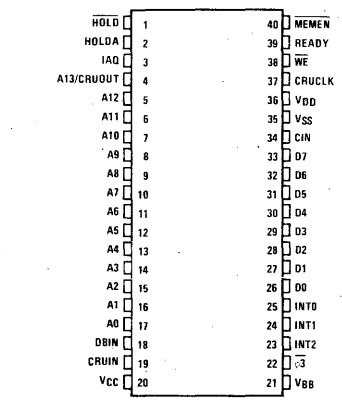
The AMI Quality Assurance Program is an ongoing activity that pervades the entire design and manufacturing process. The quality assurance function includes a special group of inspectors, organizationally separate from production. The main responsibility of these inspectors is to examine and test custom circuits and all the raw materials that go into them. The following is a partial list of the quality control checkpoints in the creation of a custom circuit. At each of these preproduction steps, meticulous checks of both design and workmanship are made.

©IC MASTER 1978



16-Bit Single Chip CPU

FEATURES



- 16-Bit Instruction Word
- Full Minicomputer Instruction Set Capability Including Multiple and Divide
- Up to 16,384 Bytes of Memory
- 8-Bit Memory Data Bus
- Advanced Memory-to-Memory Architecture
- Separate Memory, I/O, and Interrupt-Bus Structures
- 16 General Registers, 4 Prioritized Interrupts
- Programmed and DMA I/O Capability
- On-Chip Oscillator with External Frequency Option

The S9980 is a software-compatible member of AMI's S9900 family of microprocessors. Designed to minimize the system cost for smaller systems, the S9980 is a single-chip 16-bit CPU which has an 8-bit data bus, on-chip clock, and is packaged in a 40-pin package. The instruction set of the S9980 includes the capabilities offered by full minicomputers and is exactly the same as the S9900. The unique memory-to-memory architecture features multiple register files, resident in memory, which allow faster response to interrupts and increased programming flexibility. The separate bus structure simplifies the system design effort. AMI provides a compatible set of MOS memory and logic function circuits to be used with an S9980 system.

S9980 PIN ASSIGNMENTS AND FUNCTIONS

SIGNATURE	PIN	I/O	DESCRIPTION
			ADDRESS BUS
A_0 (MSB)	17	OUT	A_0 through A_{13} comprise the address bus. This 3-state bus provides the memory-address vector to the external-memory system when $\overline{MEMEN}$ is active and I/O-bit addresses and external-instruction addresses to the I/O system when $\overline{MEMEN}$ is inactive. The address bus assumes the high-impedance state when HOLDA is inactive.
A_1	16	OUT	
A_2	15	OUT	
A_3	14	OUT	
A_4	13	OUT	
A_5	12	OUT	
A_6	11	OUT	
A_7	10	OUT	
A_8	9	OUT	
A_9	8	OUT	
A_{10}	7	OUT	
A_{11}	6	OUT	
A_{12}	5	OUT	
A_{13}/CRUOUT	4	OUT	
			CRUOUT
			Serial I/O data appears on A_{13} when an LDCR, SBZ and SBO instruction is executed. This data should be sampled by the I/O interface logic when CRUCLK goes active (high). One bit of the external instruction code appears on A_{13} during external instruction execution.
			DATA BUS
D_0 (MSB)	26	I/O	D_0 through D_7 comprise the bi-directional 3-state data bus. This bus transfers memory data to (when writing) and from (when reading) the external-memory system when $\overline{MEMEN}$ is active. The data bus assumes the high-impedance state when HOLDA is active.
D_1	27	I/O	
D_2	28	I/O	
D_3	29	I/O

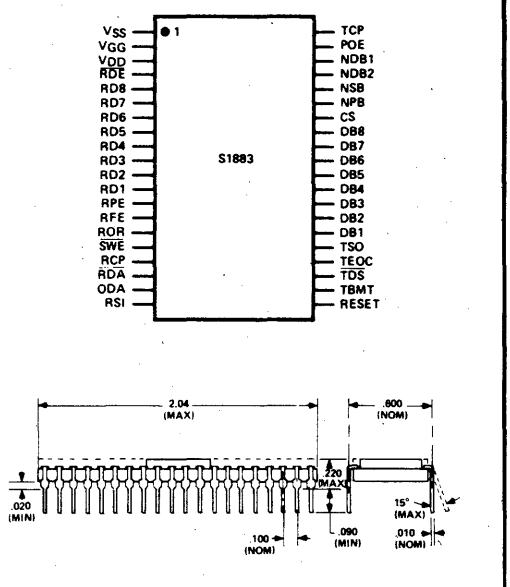
SIGNATURE	PIN	I/O	DESCRIPTION
D_4	30	I/O	
D_5	31	I/O	
D_6	32	I/O	
D_7 (LSB)	33	I/O	
			POWER SUPPLIES
V_{BB}	21		Supply voltage (-5V NOM)
V_{CC}	20		Supply voltage (5V NOM)
V_{DD}	36		Supply voltage (12V NOM)
V_{SS}	35		Ground reference
			CLOCKS
CIN	34	IN	The S9980 has an on-chip oscillator to generate the system clock (2MHz). But an option is provided to allow external system clock. CKIN is tied to +12V to use the internal oscillator. Alternately, a TTL level periodic wave of frequency equal to or less than 12MHz may be applied to CKIN. In the latter case, the internal oscillator is ignored and external frequency is used to generate the system clock (3MHz or less).
$\overline{\phi 3}$	22	OUT	Clock phase 3 ($\overline{\phi 3}$) inverted.
			BUS CONTROLS
DBIN	18	OUT	Data bus in. When active (high), DBIN indicates that the S9980 has disabled its output buffers to allow the memory to place memory-read data on the data bus during $\overline{\text{MEMEN}}$. DBIN remains low in all other cases except when HOLDA is active.
$\overline{\text{MEMEN}}$	40	OUT	Memory enable. When active (low), $\overline{\text{MEMEN}}$ indicates that the address bus contains a memory address.
$\overline{\text{WE}}$	38	OUT	Write enable. When active (low), $\overline{\text{WE}}$ indicates that memory-write data is available from the S9980 to be written into memory.
CRUCLK	37	OUT	CRU clock. When active (high), CRUCLK indicates that external interface logic should sample the output data on CRUOUT or should decode external instructions on A_0, A_1, A_{13}.
CRUIN	19	IN	CRU data in. CRUIN, normally driven by 3-state or open-collector devices, receives input data from external interface logic. When the processor executes a STCR or TB instruction, it samples CRUIN for the level of the CRU input bit specified by the address bus (A_2 through A_{12}).
INT0	23	IN	Interrupt code. Refer to Section 2.2 for detailed description.
INT1	24	IN	
INT2	25	IN	
			MEMORY CONTROL
$\overline{\text{HOLD}}$	1	IN	Hold. When active (low), $\overline{\text{HOLD}}$ indicates to the processor that an external controller (e.g., DMA device) desires to utilize the address and data buses to transfer data to or from memory. The S9980 enters the hold state following a hold signal when it has completed its present memory cycle.* The processor then places the address and data buses in the high-impedance state (along with $\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) and responds with a hold-acknowledge signal (HOLDA). When $\overline{\text{HOLD}}$ is removed, the processor returns to normal operation.
HOLDA	2	OUT	Hold acknowledge. When active (high), HOLDA indicates that the processor is in the hold state and the address and data buses and memory control outputs ($\overline{\text{WE}}$, $\overline{\text{MEMEN}}$, and DBIN) are in the high-impedance state.
READY	39	IN	Ready. When active (high), READY indicates that memory will be ready to read or write during the next clock cycle. When not-ready is indicated during a memory operation, the S9980 enters a wait state and suspends internal operation until the memory system indicates ready.
			TIMING AND CONTROL
IAQ	3	OUT	Instruction acquisition. IAQ is active (high) during any memory cycle when the S9980 is acquiring an instruction. IAQ can be used to detect illegal op codes. It may also be used to synchronize LOAD stimulus.



* If the cycle following the present memory cycle is also a memory cycle, it too is completed before S9980 enters hold state.

Universal Asynchronous Receiver/Transmitter (UART)

S1883 BLOCK DIAGRAM

PIN/PACKAGE CONFIGURATION

FEATURES

- 12.5 K Baud Data Rates
- 5-8 Bit Word Length
- Parity Generation/Checking Odd, Even, None
- Framing and Overflow Error Detection
- 1, 1.5, or 2 Stop Bits
- Double Buffered Input/Output
- Independent Transmit/Receive Rates
- Start and Stop Bits Generated and Detected
- Interchangeable with TMS6011, COM2017, TR1602, AY-5-1013
- Tri-State Outputs

FUNCTIONAL DESCRIPTION

The S1883 Universal Asynchronous Receiver Transmitter (UART) is a single chip MOS/LSI device that totally replaces the asynchronous parallel to serial and serial to parallel conversion logic required to interface a word parallel controller or data terminal to a bit serial communication network.

For asynchronous data transmission with a non-contiguous data bit stream, the UART automatically inserts a START bit preceding each character and under program control 1, 1.5, or 2 stop bits at the end of each character. To detect incoming characters in a noisy environment the UART employs a START bit detection network and allows errorless recovery of data with up to 42% distortion.

The UART will transmit or receive data characters of 5, 6, 7, or 8 bit length. Options allow the generation and checking of odd, even parity or no parity. The odd or even parity bit is automatically added to the character length for transmission. The parity bit is removed, checked and an error flag set if incorrectly received.

The data or baud rate at the receiver input and transmitter output are determined independently by external clock inputs. The clock inputs must be 16 times the data rate required at the serial input and output. The independent clocks allow for either half or full duplex operation.

The UART provides a buffer register in both the transmitter and receiver to allow a full character time for responding to a received data ready or transmit data request signal. The UART generates a MARK signal if the transmit register is not loaded with a data character and also indicates an overflow error if two characters are received without a RDA input.

TYPICAL APPLICATIONS

- Computer Peripherals
- Communication Concentrators
- Integrated Modems
- Industrial Data Transmission
- TTY Terminals
- Time Division Multiplexing

ABSOLUTE MAXIMUM RATINGS

Ambient Temperature Under Bias	0°C to +70°C
Storage Temperature	−65°C to +150°C
Positive Voltage on Any Pin with Respect to V_{SS}	+.3 Volt
Negative Voltage on Any Pin with Respect to V_{SS}	−20.0 Volt

NOTE: Stresses greater than those listed as Maximum Ratings may cause permanent damage to the device. Functional operation of the device at these or any other conditions above those indicated in the operation section of this specification are not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Universal Synchronous Receiver/Transmitter (USRT)

BLOCK DIAGRAM

PIN/PACKAGE CONFIGURATION

FEATURES

- 500 KHz Data Rates
- Internal Sync Detection
- Fill Character Register
- Double Buffered Input/Output
- Bus Oriented Outputs
- 5–8 Bit Characters
- Odd/Even or No Parity
- Error Status Flags
- Single Power Supply (+5v)
- Input/Output TTL Compatible

FUNCTIONAL DESCRIPTION

The S2350 Universal Synchronous Receiver Transmitter (USRT) is a single chip MOS/LSI device that totally replaces the serial to parallel and parallel to serial conversion logic required to interface a word parallel controller or data terminal to a bit-serial, synchronous communication network.

The USRT consists of separate receiver and transmitter sections with independent clocks, data lines and status. Common with the transmitter and receiver are word length and parity mode. Data is transmitted and received in a NRZ format at a rate equal to the respective input clock frequency.

Data messages are transmitted as a contiguous character stream, bit synchronous with respect to a clock and character synchronous with respect to framing or "sync" characters initializing each message. The USRT receiver compares the contents of the internal Receiver Sync Register with the incoming data stream in a bit transparent mode. When a compare is made, the receiver becomes character synchronous formatting a 5, 6, 7, or 8 bit character for output each character time. The receiver has an output buffer register allowing a full character time to transfer the data out. The receiver status outputs indicate received data available (RDA), receiver overrun (ROR), receive parity error (RPE) and sync character received (SCR). Status bits are available on individual output lines and can also be multiplexed onto the output data lines for bus organized systems. The data lines have tri-state outputs.

The USRT transmitter outputs 5, 6, 7, or 8 bit characters with correct parity at the transmitter serial output (TSO). The transmitter is buffered to allow a full character time to respond to a transmitter buffer empty (TBMT) request for data. Data is transmitted in a NRZ format changing on the positive transition of the transmitter clock (TCP). The character in the transmitter fill register is inserted into the data message if a data character is not loaded into the transmitter after a TBMT request.

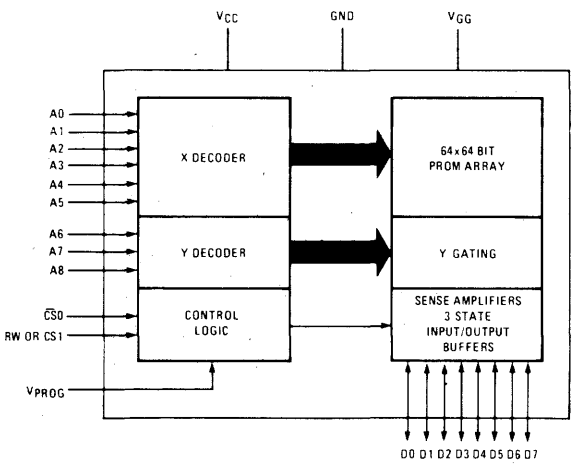
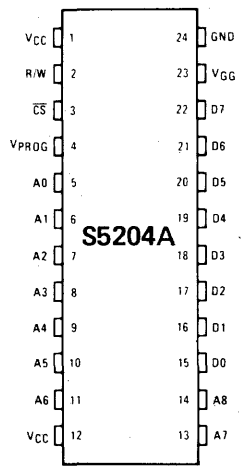
4096 Bit (512×8) Erasable and Electrically Reprogrammable ROM



Features

- ☐ On-Board Programmability
- ☐ Fast Access Time — 750ns Max.
- ☐ High Speed Programming — Less than 1 Minute for all 4096 Bits
- ☐ Programmed with R/W, CS and V_{PROG} Pins
- ☐ Completely TTL Compatible — Excluding the V_{PROG} Pin during Read or Write
- ☐ Ultraviolet Light Erasable — Less than 10 Minutes
- ☐ Static Operation — No Clocks Required
- ☐ Three-State Data I/O
- ☐ Standard Power Supplies — +5V and -12V
- ☐ Mature P-Channel Process

General Description



The S5204A is a high speed, static, 512x8 bit, erasable and electrically programmable read only memory designed for use in bus-organized systems. Both input and output are TTL compatible during both read and write modes. Packaged in a 24-pin hermetically sealed dual in-line package, the bit pattern can be erased by exposing the chip to an ultraviolet light source through the transparent lid, after which a new pattern can be written.

Block Diagram

77675

Pin Configuration

877254

ABSOLUTE MAXIMUM RATINGS

Voltage on any pin relative to V_{SS} except the V_{PROG} pin	+0.3V to -20V
Voltage on the V_{PROG} pin relative to V_{SS}	+0.3V to -60V
Operating Temperature	0°C to +70°C
Storage Temperature (programmed)	-55°C to +85°C
Storage Temperature (unprogrammed)	-55°C to +150°C

Typical Applications

- ☐ ROM Program Debugging
- ☐ Code Translation
- ☐ Microprogramming
- ☐ Look-up Tables
- ☐ Random Logic Replacement
- ☐ Programmable Waveforms
- ☐ Character Generation
- ☐ Electronic Keyboards

NOTE: This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields, however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

INTERFACE DESCRIPTION

Pin	Label	Function
(15)	D0	**Data Lines** – with the R/W line selected for Read (V_{IH}), the Data Line (D0 through D7) are set to reflect the contents of the selected memory location. When the R/W line is set for Write (V_{IL}), the Data Lines are stored at the addressed location of the 5204A when V_{PROG} is present. The Data Bus output drivers are three-state devices that remain in the high impedance (off) state whenever CS is in the V_{IH} state or when R/W is in the V_{IL} state.
(16)	D1	
(17)	D2	
(18)	D3	
(19)	D4	
(20)	D5	
(21)	D6	
(22)	D7	
(2)	R/W	**Read/Write** – When this input line is set to V_{IH}, the device is in the Write mode, a low (V_{IL}) signal puts it into the Read mode.
(3)	CS	**Chip Select** – This input line must be set to V_{IL} for a Read or Write operation to be performed. When it is High (V_{IH}) the output data bus is set to a high-impedance three-state condition.
(4)	V_{PROG}	**Program** – In the Write mode, a 50Volt programming pulse at this input causes the data at the Data Lines to be stored in the selected address location. This pin should be tied to V_{CC} for normal Read operations.
(5)	A0	**Address Lines** – These lines select the 8 bit word in memory for Read or Write operation.

CONTROL FUNCTION TRUTH TABLE

CS	R/W	V_{PROG}	MODE	OUTPUTS
0	1	V_{PROG}	Write	Active Data Inputs
0	0	V_{CC}	Read	Active
1	X	X	Standby	Floating

OPERATION

Initially, and after each erasure, all bits of the 5204A are in the LOW state (output 0 volts). Data is stored by selectively programming a HIGH into the desired bit locations. The R/W input (pin 2) is used to select the desired mode of operation. When the R/W input is HIGH the chip is in the write enable mode of operation. The outputs (D_0 – D_7) are disabled (floating) with the corresponding pins becoming the data inputs. The word address is selected in the same manner as in the Read mode. Data to be programmed is presented 8 bits in parallel and after the address and data are set up a programming pulse (V_P = - 50 volts) is applied. V_{PROG} electrically writes the data into the memory array. Writing may be inhibited by deselecting the chip with the CS input at a HIGH during the write cycle. This feature allows true "on board" programming in bus organized systems where the R/W and V_{PROG} inputs are common and the device to be programmed is selected by means of the chip select input as during read operations.

The amount of program energy required to insure memory retention may be defined as a function of the number of program pulses (N) times the program pulse width (t_{pw}) ($N \times t_{pw} \geq 60$ msec). This means if a 3 ms pulse is used, 20 program pulses are required, and if a 5 ms pulse is used 12 program pulses are required.

The read operation is accomplished by a LOW at the R/W input with the program input connected to V_{SS} potential. True data (data out = date in) is valid after the address is stable. The CS input will disable (float) the outputs when HIGH to allow capability with bus organized systems.

Erasure is accomplished by exposing the array to a 2537Å ultra-violet light source (such as Ultra-Violet Products, Inc. Lamp Model S52 or UVS-54, Turner Designs PROM Eraser, Model 30 or equivalent) for a period of 7 to 10 minutes. The clear optical lid should be approximately one inch away from the lamp tubes.

THE FORMULATOR LINE OF F8 AND F3870 DESIGN AIDS

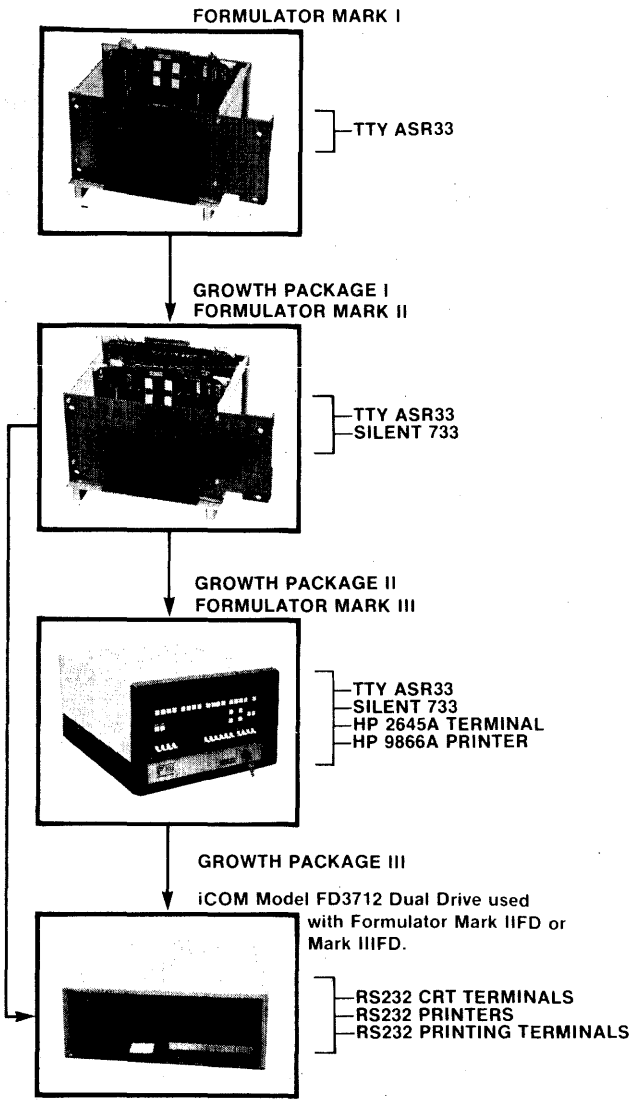
INTRODUCTION

The Microprocessor system designer can now create his own hardware and software development systems for the F8 and F3870 by selecting modular subassemblies from Fairchild's Formulator line of F8 and F3870 design aids. He may start development with a Mark I singleboard system, then expand to more sophisticated Mark II or Mark IIFD development systems that can handle both software and hardware development. Or he may graduate to a complete Formulator Mark III with intelligent front panel, power supply, and accessories or to the top of the line Formulator Mark IIIFD with floppy disk drives.

Three growth packages plus a selection of optional modules provide a practical method for upgrading the single-board Mark I to either the Mark II or Mark IIFD or to the maximum system configuration Mark III or Mark IIIFD. Using the growth packages, the designer can begin sophisticated system application programs at very low cost and then upgrade his development tools in relatively inexpensive steps, if he desires to do so at a later time.

The most elementary configuration, called the Formulator Mark I, includes a Processor module that contains an F8 CPU, Program Storage Unit that includes Fairbug monitor, Dynamic and Static Memory Interface circuits, 1024 bytes of random access memory, and the necessary buffers and other components for hardware development. It also includes a 13-slot card cage, an I/O cable kit, and a power cable.

The second level, the Formulator Mark II, includes all of the Mark I components plus a memory board with 16 kilobytes of RAM and the complete Formulator Operating System, designated FOS. FOS gives the user complete software development capability, including an assembler, editor, and debug package, and drivers for a teletype or the TI Silent 733 terminal.



The third level, the Formulator Mark IIFD, is identical to the Mark II with the addition of interface cards and cables for an iCOM FD3712 dual-drive floppy disk system and Fairchild F8-DOS-III Floppy Disk Operating System.

The fourth level, the Formulator Mark III, includes an intelligent front panel, a serial communications module, a quad I/O module, an attractive cabinet, and a power supply. Also included are 16 kilobytes of RAM, the Formulator Processor Module, and the Formulator Operating System.

The top of the line is the Formulator Mark IIIFD. This microcomputer is identical to the Mark III except it interfaces to the iCOM dual drive floppy disk.

Three growth packages are available for Mark I, Mark II, and Mark III expansion. Growth Package I upgrades the Mark I system to the Mark II level. Growth Package II converts the Mark II to the full Mark III level. Growth Package III upgrades either the Mark II or Mark III to the Mark IIFD or the Mark IIIFD floppy disk configurations.

Other boards are available as options for all five Formulator configurations to increase the flexibility of the units by adding to their capabilities. These include 4-kilobyte RAM, 4-kilobyte PROM, and 16-kilobyte RAM boards, as well as and I/O light board, a communications board with UART, a parallel-byte board for peripheral interface, and a PROM programmer.

FORMULATOR GROWTH PATHS

©IC MASTER 1978

FORMULATOR MARK I

The first member of the Formulator family, the Formulator Mark I, is a basic microcomputer development tool providing the hardware necessary to build F8 or F3870 prototype systems. Included in the basic system is the Formulator Processor Module with the F8 CPU, Static Memory Interface, Dynamic Memory Interface, and Program Storage Unit devices. The Fairbug debug program, a 1K-byte monitor debug package, is included in the Program Storage Unit on the Processor Module. Fairbug provides the Mark I with sufficient debug capability to load a program, examine registers, monitor and alter memory locations, store a program on an external file, and generate a tape suitable for burning PROM memory devices. The Mark I also comes equipped with a 13-slot card cage and motherboard for attaching the modular Formulator printed circuit boards. Three slots are wired for the console control modules and one is dedicated to the Processor Module. The other nine connectors are general purpose slots which can accept additional Formulator modules for system expansion. Cables and documentation are also included in the F8 Formulator Mark I system, including a peripheral interface cable which can connect the Mark I to a Teletype ASR33 or TI Silent 733 for external communication.

THE FORMULATOR PROCESSOR MODULE

The Formulator Processor Module is the heart of the Formulator family of development systems. As illustrated in the block diagram below, the 10½" × 7½" Processor Module contains a Central Processor Unit (F3850 CPU), a Program Storage Unit (F3851A PSU) with the Fairbug monitor, a Static Memory Interface circuit (F3853 SMI), a Dynamic Memory Interface circuit (F3852 DMI), a 1K-byte RAM memory, and a peripheral interface circuit. Also included is the circuitry necessary to drive the Formulator bus for easy expansion of system functions. The 32 bidirectional I/O lines are brought out to the top edge connector; bus signals are brought to a connector on the bottom of the board. The board connector plugs into the Formulator motherboard where the signals are bussed to twelve other sockets. The peripheral interface signals are brought out to a special connector mounted on the Processor Module. They include both a 20 mA current loop and an RS232 interface circuit.

Two interrupt levels are available on the Formulator Processor Module, one from the F3851A PSU and the other from the F3853 SMI. The on-board F3852 DMI allows dynamic memory refresh and direct memory access functions to be incorporated into expanded memory systems.

Switches on the Processor Module change the page address of the 1K-byte RAM memory. Additional switches are provided to change the port addresses of the PSU circuit, enable and disable the Fairbug program, select the clock mode (LC, crystal, or external), enable the interrupt priority, and select serial interface devices (RS232 or current loop).

The Fairbug program, located in the F3851A PSU communicates with an ASCII serial device, reads data from a parallel paper tape reader, and punches tape. The Fairbug program also performs a debug function allowing users to examine and alter internal registers and memory.

PROCESSOR MODULE

©IC MASTER 1978

FORMULATOR MARK II

The second member is the Formulator Mark II. This unit is a low cost microcomputer software and hardware development tool. It includes the basic hardware required to develop a system, as well as the necessary software tools to develop F8 and F3870 code. The Mark II consists of all the components of the Mark I, namely the Processor Module, card cage and motherboard, cable kit, and the Fairbug debug program, as well as an additional 16K-byte RAM module. Also a part of the Mark II is the Formulator Operating System, including the editor, relocating assembler, and debug package to allow the generation of the source codes and to create and check out the object codes. Peripheral interfaces are also available to connect the Mark II to a TI Silent 733 or Teletype ASR33.

MARK II FORMULATOR OPERATING SYSTEM—FOS

The software for the Formulator products is specifically designed to assist engineers and programmers during the development phase of a microcomputer-based system. Designated the Formulator Operating System (FOS), this software package consists of a monitor, an editor, an assembler, a linking loader, a debug package, and several utility programs.

The editor assists the user in the creation of a source file, which the assembler then converts into an object file ready for loading into the system. This object file may, at the option of the user, be a relocatable file. If several such relocatable object files exist, they may be combined by the linking loader and assigned absolute addresses at loading.

The debug portion of the Mark II FOS allows users to test for fast and efficient program testing, for setting software breakpoints, and for examining and altering memory, registers, and I/O ports.

Unlike other development systems with limited storage capability, the Formulator has enough memory so that the editor, relocating assembler, and debug packages are simultaneously resident, with transfer from one to the other controlled by the monitor. Thus, a program may be created, edited, assembled, and debugged without ever having to reload the system software, since the user may switch from the editor to the assembler to the debug program directly from the monitor.

The Formulator software also includes utility programs which perform specific functions. One, for instance, generates a file for producing a ROM code. Another creates a file needed by a PROM programmer. These utility programs are loaded into the system under the control of the monitor.

The combined effect of the interrelated portions of the Formulator Operating System is the rapid generation and checkout of F8 and F3870 microcomputer-based systems. These programs greatly simplify the effort required to develop and alter the end user software, making it easy to design and debug a system breadboard, easy in terms of reduced time and manpower.

©IC MASTER 1978

FORMULATOR MARK IIFD

The third member is the Formulator Mark IIFD, a floppy-disk based low-cost microcomputer software and hardware development tool. It includes the basic hardware required to develop a system, as well as the necessary software tools to develop F8 and F3870 code. The Mark IIFD consists of all the components of the Mark I, namely the Processor Module, card cage and motherboard, cable kit, and the Fairbug debug program, as well as an additional 16K-byte RAM Module. The F8-DOS-III is also a part of the Mark IIFD. It includes a floppy-disk file manager, editor, relocating assembler, and debug package to generate the source codes and to create and check out the object codes. The Mark IIFD can communicate with teletype ASR33 and other standard RS232 CRT or printing terminals.

MARK IIFD FLOPPY-DISK OPERATING SYSTEM — F8-DOS-III

The software for the Formulator products is specifically designed to assist engineers and programmers during the development phase of a microcomputer-based system. Designated the F8 DOS-III, this software package consists of a floppy-disk monitor, an editor, a relocating assembler, a linking loader, a debug package, and utility programs.

The disk monitor provides all of the necessary commands for fast and efficient file management during the creation, editing, assembly, and debugging of applications programs.

The editor assists the user in the creation of a source file, which the assembler then converts into an object file ready for loading into the system. This object file may, at the option of the user, be a relocatable file. If several such relocatable object files exist, they may be combined by the linking loader and assigned absolute addresses at loading.

The debug portion of the F8-DOS-III provides for fast and efficient program testing. Under software control, the user can set software breakpoints, and examine and alter memory, registers, and I/O ports.

Unlike development systems with limited storage capability, the Formulator Mark IIFD has enough memory so that the editor, assembler, and debug packages are resident as needed with transfer from one to the other controlled by the disk monitor. Thus, a program may be created, edited, assembled, and debugged without ever having to externally reload the system software, since the user may switch from the editor to the assembler to the debug program directly from the disk monitor.

The Formulator software also includes utility programs which perform specific functions. One, for instance, generates a file for producing a ROM code; another creates a file needed by a PROM programmer. These utility programs are loaded into the system under the control of the disk monitor.

The combined effect of the interrelated portions of the F8 DOS-III is the rapid generation and checkout of F8 and F3870 microcomputer-based systems. These programs greatly simplify the effort required to develop and alter the end-user software, making it easy to design and debug a system breadboard, easy in terms of reduced time and manpower.

FORMULATOR MARK III

The fourth level of microprocessor development equipment is the Formulator Mark III, offering all of the design assistance required to develop F8 or F3970 based systems. The combination of hardware, software, and firmware offered by the Mark III assists the designer from the generation of source programs through the development of a prototype system. The Mark III is a modular microcomputer that accommodates a variety of memory, input/output, and communication configurations to form a new and powerful development system. It contains all of the components of the Mark II—the Processor Module, card cage and motherboard, cable kit, the Fairbug debug program, 16K bytes of RAM, and the Formulator Operating System. In addition, the Mark III includes a Quad I/O Module with four I/O ports and two interrupts, a Communications Module with an on-board UART, a universal breadboard for building user hardware configurations, an extender module, and an intelligent operator's panel. Power supplies for the Mark III may be either 100 volts, 115 volts, or 220 volts at 50/60 Hz. Peripheral interfaces are available to connect the Mark III with a TI Silent 733, a Teletype ASR33, or an HP 2645A Mini-Data Station.

INTELLIGENT OPERATOR'S PANEL

Perhaps the most unique feature of the Mark III Formulator is the intelligent operator's panel, an array of lights and switches designed to give the user access to vital registers and memory locations within the microcomputer; thus enabling an important interaction between the user and the system hardware and software.

The benefits of having a firmware controlled front panel are extensive. In addition to performing the normal front panel operations, such as examining and loading the contents of memory, the user's console can also perform some very complicated functions. Chief among these are the front panel's relocatable initial program load capability, its test function, and the real time hardware breakpoint feature.

The self test function is initiated by the user by merely depressing a single switch on the front panel. The console then begins to check the electronics in the Formulator. When an error condition is detected, the LED indicators on the display indicate the type of error and its location.

Another feature of the front panel is its ability, under operator control, to set hardware breakpoints and to vary the number of times a memory location may be accessed before the break-in program execution occurs. This aids the user in performing fast, efficient debugging of his software.

MARK III FORMULATOR OPERATING SYSTEM

Like the Mark II Formulator Operating System, the Mark III FOS consists of a monitor, an editor, an assembler, a linking loader, a debug package, and several utility programs. In addition to the functions performed by each of these portions of the FOS in a Mark II system, the Mark III FOS includes the capability to set hardware breakpoints. It also contains a trace feature in the debug package which lets the user turn tracepoints on and off during the debug operation.

Two identical versions of the Formulator Operating System are available with the Formulator Mark III. One operates in the lower portion of memory and another operates in upper memory. The Low Memory Operating System resides in memory locations 1000 to 3FFF (Hex). Most of the lower 4K bytes of memory is reserved for user programs. The High Memory Operating System occupies locations with the hexadecimal addresses D000 to FFFF and uses the portion of memory from LC000 to D000 to store the symbol table. With this system, the user has up to 48K bytes of continuous memory addresses available, eliminating the need for splitting programs larger than 4K bytes.

©IC MASTER 1978

FORMULATOR MARK IIIFD

The top of the line in microprocessor development equipment is the floppy-disk-based Formulator Mark IIIFD, offering all of the design assistance required to develop F8 or F3870 based systems. The combination of hardware, software, and firmware offered by the Mark IIIFD assists the designer from the generation of source programs through the development of a prototype system. The Mark IIIFD is a modular microcomputer that accommodates a variety of memory, input/output, and communication configurations to form a new and powerful development system. It contains all of the components of the Mark IIFD, the Processor Module, card cage and motherboard, cable kit, the Fairbug debug program, parallel interface, PROM boot loader, 16K bytes of RAM, and the F8-DOS-III disk operating system. In addition, the Mark IIIFD includes a quad I/O module with four I/O ports and two interrupts, a communications module with an on-board UART, a universal breadboard for building user hardware configurations, an extender module, and an intelligent operator's panel. Power supplies for the Mark IIIFD may be either 100 volts, 115 volts or 220 volts at 50/60 Hz. The Mark IIIFD can communicate with teletype ASR33 or other standard RS232 glass or printing terminals.

INTELLIGENT OPERATOR'S PANEL

A unique feature of the Mark IIIFD Formulator is the intelligent operator's panel, an array of lights and switches designed to give the user access to vital registers and memory locations within the microcomputer, thus enabling an important interaction between the user and the system hardware and software. The front panel functions of the Mark IIIFD are identical to those described in the Mark III section.

MARK IIIFD FLOPPY DISK OPERATING SYSTEM

The software for the Formulator products is specifically designed to assist engineers and programmers during the development phase of a microcomputer-based system. Designated the F8-DOS-III, this software package consists of a floppy disk monitor, an editor, a relocating assembler, a linking loader, a debug package, and utility programs. The disk monitor provides all of the necessary commands for fast and efficient file management during the creation, editing, assembly, and debugging of applications programs.

The editor assists the user in the creation of a source file, which the assembler then converts into an object file ready for loading into the system. This object file may, at the option of the user, be a relocatable file. If several such relocatable files exist, they may be combined by the linking loader and assigned absolute addresses at loading.

The debug portion of the Mark III F8-DOS-III provides for fast and efficient testing. Under Software Control, the user can set software and hardware breakpoints, and examine and alter memory, registers, and I/O ports.

Unlike development systems with limited storage capability, the Formulator Mark IIIFD has enough memory so that the editor, assembler, and debug packages are resident as needed with transfer from one to the other controlled by the disk monitor. Thus, a program may be created, edited, assembled, and debugged without ever having to externally reload the system software, since the user may switch from the editor to the assembler to the debug program directly from the disk monitor.

The Formulator software also includes utility programs which perform specific functions. One, for instance, generates a file for producing a ROM code; another creates a file needed by a PROM programmer. These utility programs are loaded into the system under the control of the disk monitor.

The combined effect of the interrelated portions of the Formulator F8-DOS-III is the rapid generation and checkout of F8 and F3870 microcomputer-based systems. These programs greatly simplify the effort required to develop and alter the end-user software, making it easy to design and debug a system breadboard, easy in terms of reduced time and manpower.

F8-DOS-III DESCRIPTION

The Formulator F8-DOS-III operating system provides floppy-disk bulk storage capability for Fairchild's Formulator Mark IIFD and Mark IIIFD F8 microcomputers when used with up to four plug-compatible iCOM® series FD 360, FD3700 and Frugal Floppies™ providing for over one megabyte of total storage capacity.

F8-DOS-III provides a powerful and complete development software package with batch operation, linking loader, and relocating assembler, and provides an easy to use, reliable, fast and extremely efficient capability for auxiliary program and data storage during F8 and F3870 software development or in end-user applications.

iCOM® Advertised FD3700 Series Features	F8-DOS-III SUMMARY			
	Disk Monitor	**Editor**	**Relocating Assembler**	**Real-Time Debugger**
Fully IBM 3740 media and format compatible	Assemble (Relocating)	Move Line	No-List Option	Symbolic Debugging
Full formatter and controller built-in	Load (Linking)	Copy Line	No-Object Option	Set Up to 8 Breakpoint
Full sector Read/Write buffers allow	List Directory	Bottom	Error Messages	Clear Breakpoint
asynchronous or DMA data transfer	Print File	Change	Invalid Label	Clear All Breakpoints
Drive and diskette Write Protect capability	Rename File	Delete	Duplicate Label	Continue Execution
Positive latching door mechanism	Create File	File	Invalid Op Code	Go To Location
Up to 4 drives with no software or hardware	Delete File	Find String	Operand Error	Return to Monitor
modifications	Copy File	Insert	Syntax Error	Single Step
MTBF in excess of 2300 hours (FD 3712 dual	Copy Disk	Locate String	Undefined Symbol	Trace On Long
drive)	GenMod (Created	Next	Expression Storage	Trace on Short
Plug-in convenience allows MTTR of 18	Linked File)	Replace	Overflow	Trace Off
minutes	Edit Mode	Tab	Relocatability	Display Memory
Front panel LED status indicators	Load (Absolute)	Top	Error	Display Register
LED drive select indicators	DeBug Mode	Type	Pseudo Operand	Display Port
Fully retracting head and pressure pad for	Assign Virtual I/O	Up	Error	Store Memory
maximum diskette life	Burn PROM		Cross Reference	Store Register
50 pin flat ribbon cable with 3M interface	Convert			Store Port
connector—FD 360 compatible	ROM Dump			

FORMULATOR GROWTH PACKAGES

The Mark I, Mark II, and Mark III Formulator systems previously described are all upwards compatible. The Mark I can be expanded to become a Mark II; likewise, the Mark II may be developed into a Mark III. In addition, a Mark II can be expanded to a Mark IIFD and a Mark III into a Mark IIIFD. This means that a microprocessor system designer may enter the microcomputer design at a level which best matches the needs at hand—amount of available money, time, microprocessor experience—and be able to increase the Formulator's capabilities as his needs grow. Three growth packages are available to Formulator product owners. Growth Package 1 converts a Mark I system to a Mark II; Growth Package 2 extends the capabilities of the Mark II into the Formulator Mark III, and Growth Package 3 extends a Mark II or III into a Mark IIFD or IIIFD.

Growth Package I
- 16K-Byte RAM Module
- Mark II Formulator Operating System

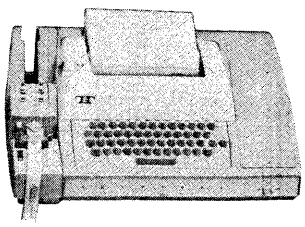
Growth Package 2
- Quad I/O Module
- Communications Module
- Power Supply
- Fan
- Console Control Modules
- Internal Cable Wiring
- Universal Breadboard
- Extender Module
- I/O Cable Assembly
- Communications Module to Peripheral Cable
- Mark III Formulator Operating System

Growth Package 3
- Parallel Interface Module
- PROM Boot Loader Module
- F8-DOS-III System Diskette

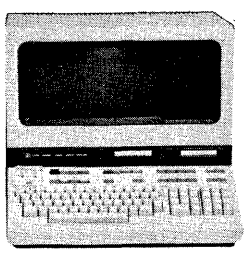
©IC MASTER 1978

PERIPHERAL OPTIONS

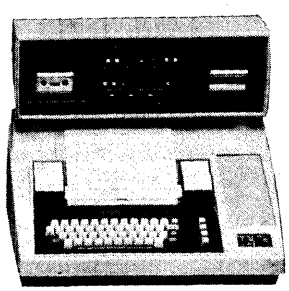
The Formulator Mark II systems interface with either a Teletype ASR33 with the auto read/auto punch option or a TI Silent 733 ASR with the ADC option. The teletype terminal provides a paper tape based system, while the 733 allows file storage on magnetic tape cassettes. To decrease load times, a Remex high speed paper-tape reader (or equivalent) may be used with either peripheral unit.



The Formulator Mark III provides an interface for the HP Mini-Data Station as well. This high speed unit combines the efficiency of the magnetic tape cartridges with an intelligent terminal and thermal line printer to allow the rapid development and debugging of application programs.



The Formulator Mark IIFD and IIIFD systems interface with any standard RS232 glass terminal and printer or printing terminal to offer maximum peripheral cost/speed flexibility.



HP MINI-DATA STATION

The HP 2645A Mini-Data Station features an interactive CRT Terminal with high resolution display and a fully integrated mass storage capability, making it easy to use both on- and off-line. It uses 2½″ × 3¼″ × ½″ magnetic cartridges which store up to 110 kilobytes of formatted data. The Mini-Data Station has two mini cartridge drives, allowing for a total of 220 kilobytes of data storage on matnetic tape. Thus, all files—both operating system and user files—are resident on the magnetic tape. Loading and storing files is accomplished by reading and writing onto the cartridge. The user's time is decreased and efficiency increased when the magnetic tapes are used.

The 2645 Mini-Data Station comes equipped with three data cartridges, an Owner's Manual, and an Installation and Service Manual.

HP 9866A PRINTER SUBSTATION

The HP 9866A line printer is a moderately priced, high performance companion to the HP 2645A Mini-Data Station, providing a permanent record of the contents of the Mini-Data Station display and memory for future use. The printer operates at up to 240 lines per minute with a maximum line width of 80 characters. The character set consists of 64 alphanumeric characters generated by a 5 × 7 dot matrix. Since a thermal printing mechanism is used to make this printer quiet enough for normal office use, thermal sensitive paper is required. This paper is 8¾ inches wide and available in 250 foot rolls.

The 9866A thermal printer comes equipped with two rolls of paper, a power cord, an interface card and cable, and an Instruction Manual.

iCOM F3712 DUAL FLOPPY DISK

The iCom FD3700 Series Floppy Disk System for microcomputers continues the tradition fo the iCOM FD360. The FD3700 brings to the OEM, and to the development lab, proven reliability and popular features, while incorporating advanced styling and new convenience items.

The iCOM FD3700 Series features the following:

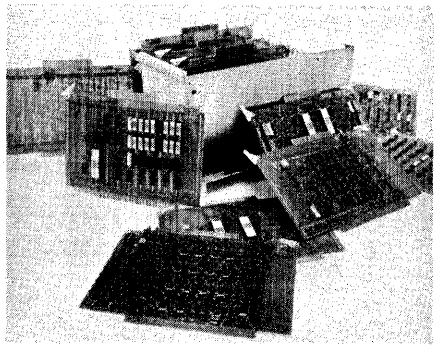
- Fully IBM 3740 media and format compatible
- Full formatter and controller built in
- Full sector read/write buffers allow asynchronous or DMA data transfer
- Drive and diskette write-protect capability
- Positive latching door mechanism
- Up to four drives with no software or hardware modifications
- MTBF in excess of 2300 hours (FD3712 dual drive)
- Plug-in convenience allows MTTR of 18 minutes
- Front panel LED status indicators
- LED drive select indicators
- Fully retracting head and pressure pad for maximum diskette life
- 50-pin flat ribbon cable with 3M interface connector—FD360 compatible

iCOM Performance features are as follows:

- Disk speed 360 RPM ± 1.5%
- 10 ms track-to-track access time
- 40 ms head load time
- 5 ms sector read/write time
- 83 ms average latency time
- 700 ms automatic head unload time
- 1 ms interrecord time

Power Requirements Are:

110-125 V_{ac}, 60 Hz, 200 W max
Optional 220-240 V_{ac}, 50 Hz, 200 W is available



©IC MASTER 1978

OPTIONAL FORMULATOR MODULES

Expansion of the Formulator microcomputers need not occur along the path indicated by the growth packages. Optional Formulator modules are available to expand RAM, PROM I/O, and communications, so the user can develop a custom system which is perfectly suited to his specific needs. These optional modules may be attached to the Formulator via the 13 card slots in the motherboard. The first three slots are dedicated to front panel operations of the Mark III. Another slot is reserved for the Processor Module. The remaining nine slots are linked on a common bus whose signals are compatible with the modules themselves. Additional system functions may be easily added to any Formulator system by simply plugging in one of the modules. Thus, the initial Formulator investment is preserved. Nothing needs to be discarded as demands upon the system increase. Unless otherwise noted, all of the following optional modules are available to update any Mark I, Mark II, Mark IIFD, Mark III, or Mark IIIFD system to meet expanded requirements.

Optional Modules

- 4K-Byte RAM Module
- 16K-Byte RAM Module
- Quad I/O Port Module
- 4K-Byte PROM Module
- Communications Module
- Byte Parallel Interface Module
- ROM Simulation Module
- Universal Breadboard
- Extender Module
- I/O Light Display Board

4K-BYTE RAM MODULE

The 4K-Byte Ram Module simplifies memory expansion in the Formulator Development Systems. Fully compatible with all Formulator bus signals, this board adds 4096 bytes of random access memory (using 2102 type static RAMs) to a system. Switches mounted on the printed circuit board allow the user to select the upper four address bits, so multiple memory modules may be used in a system. A write-protect switch puts the memory in a read-only mode at the user's discretion. Board dimensions are 10½" × 7½".

16K-BYTE RAM MODULE

The 16K-Byte RAM Module provides additional modularly expandable memory for the Formulator Development System. Fully compatible with all Formulator bus signals, this board adds 16 kilobytes of random access memory (4K N-MOS Dynamic RAM) to a system. Switches mounted on the printed circuit board allow the user to select the upper two address bits, so multiple memory modules may be used in a system. Four write-protect switches put the memory in a 'read only' mode at the user's discretion. The refresh of the dynamic memory is controlled by the F3852 Dynamic Memory Interface circuit mounted on the Processor Module. The refresh cycles are performed during unused data bus periods, and do not interfere with normal system timing. The board dimensions are 10½" × 7½".

4K-BYTE PROM MODULE

Additional memory expansion in the Formulator systems may be easily performed with the use of the 4K-Byte PROM Module. This board adds 4096 bytes of nonvolatile memory storage capability. It provides 16 sockets for the Fairchild 93446 TTL fuseable link 512 × 4-bit PROMs configured in a 4-kilobyte array. Four switches mounted on the printed circuit board allow the memory page to be switch selectable. All data bus and control bus signals are compatible with the Formulator system, so the board plus directly into the Formulator motherboard. The 93446 PROM devices may be programmed by the Formulator PROM Programmer. The board dimensions are 10½" × 7½".

QUAD I/O PORT MODULE

The Quad I/O Port Module makes expanding the Formulator I/O capability an easy task. This board uses existing F8 I/O ports, so actual F8 signal levels are brought out to the edge connector on the top of the module. This module has two F8 circuits, each with two I/O ports, one interrupt level, and one programmable timer. Thus, a total of four ports (32 bits), two interrupt levels, and two timers are available to the user. Switches mounted on the card allow the user to select the I/O port addresses and the interrupt vector addresses for each F8 circuit. Thus, since each board may use different I/O ports, multiple boards may be used in a system. The board dimensions are 10½" × 7½".

COMMUNICATIONS MODULE

The Communications Module provides the electrical interface for any one of three types of serial peripheral devices, a standard teletype 20 mA current loop, RS-232 interface, or a TTL compatible device. An on board UART (Universal Asynchronous Receiver Transmitter) is used to perform the conversion between the 8-bit parallel microcomputer data and the serial signal, thus permitting high speed data transfer. Thirteen baud rates, ranging from 50 to 9600 baud, can be set from switches mounted on the card. A crystal is used to ensure accurate timing. The UART-microcomputer interface is maintained via two F8 I/O ports, also located on the printed circuit board. The F8 timer and interrupt logic are also available to the user, with the interrupt address vector and F8 I/O port numbers switch selectable. Board dimensions are 10½" × 7½".

I/O LIGHT DISPLAY BOARD

The I/O Light Display Board monitors the status of the F8 I/O signals of either the Formulator Processor Module or the

©IC MASTER 1978

Formulator Quad I/O Module. Mounted on the printed circuit cards are red LEDs, grouped in two rows of twenty, allowing up to four I/O ports plus power supplies to be viewed simultaneously. On-board drivers provide sufficient current levels to drive the LEDs. Additional lights on the board show the status of the external interrupts. The board dimensions are 10½" × 4½".

BYTE PARALLEL INTERFACE MODULE

The Byte Parallel Interface Module interfaces the Formulator system to external devices in a parallel format. This 10½" × 7½" module creates a data bus and a control bus for passing information to and from the system. The bidirectional data bus can be used for either 8- or 16-bit parallel words. The 8-bit control bus synchronizes data transfer to and from the Formulator system. The F8 I/O ports. One level of F8 interrupt logic and one F8 interval timer are also available to the user. On-board switches select the F8 interrupt address vector and the F8 I/O port addresses. The signal levels for the device interface are given below.

Receive

V_{IL}	I_{IL}	V_{IH}	I_{IH}	V_{CC}
0.4V	−0.2mA	5.25V	25 μA	5.25V

Drive

V_{OL}	I_{OL}	V_{OH}	I_{OH}	V_{CC}
0.5V	48mA	2.4V	−10mA	4.75V

ROM Simulation Module

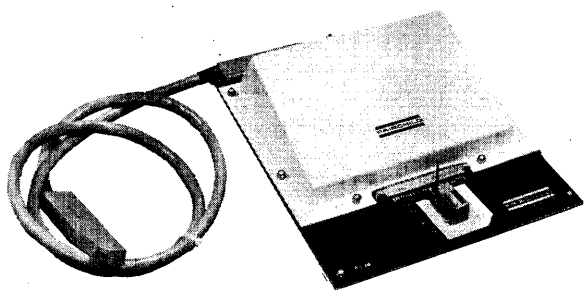
The ROM Simulation Module allows the user to interface the F3851A and F3856 Program Storage Units to the Formulator systems. Two of these 40-pin devices may be inserted in each ROM Simulation Module, creating an excellent environment for checking out ROM codes stored on the PSUs.

EXTENDER MODULE

During the checkout of the user's own breadboard systems, the Formulator Extender Module can be used to facilitate access to the user's hardware configuration contained on the universal breadboard. The 10½" × 7½" extender module plugs directly into the Formulator motherboard, and the module to be examined attaches to the 100-pin connector on the top edge of the extender card. Thus, the user's module is elevated above the other modules in the Formulator card cage for easy access.

UNIVERSAL BREADBOARD

The universal breadboard is an empty Formulator module board which can aid in the development of the user's own breadboards. It is a 10½" × 7½" Formulator motherboard-compatible module which is predrilled to accept standard 14, 16, 18, 22, 24, and 40-pin dual inline packages. It will accomodate forty-four 16-pin packages. With the universal breadboard, the Formulator user may design his own breadboard configuration of non-microprocessor circuits while in constant contact with the microprocessor development tools of the Formulator.



PROM PROGRAMMER

The ability to easily program permanent memory devices is essential to any microprocessor design. The Formulator PROM Programmer connects to a Quad I/O Module within either a Formulator Mark II or a Formulator Mark III, permitting the programming of any of the following fuseable link or ultraviolet light eraseable PROMs from a pattern stored in the Formulator memory.

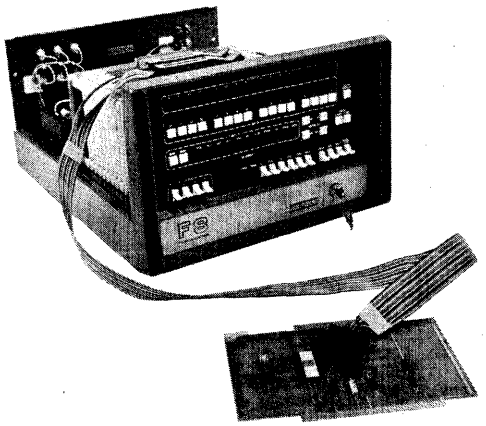
The 11" × 12" × 4" PROM Programmer is driven by a utility program contained within the Formulator Operating System and features a simple, easy to use command set. The commands, entered into the PROM Programmer from the Formulator peripheral via the keyboard, allow the user to transfer data from a PROM to memory, burn a PROM, verify a PROM pattern, manually enter a single byte of data, and display PROM locations using the system software. The programming idiosyncrasies of each PROM are contained in software look-up tables to relieve the user of intricate repetitious set-up. The procedure is simply to identify the PROM type (like 93448) and the PROM parameter look-up table is automatically invoked, defining such things as number of words, word bit length, burn time, wait time, retry conditions, etc. The programming is convenient enough to allow the PROM Programmer to be used in a production environment.

Included in the basic system are two socket boards, one for the Fairchild 93436/93446 PROMs and one for the 93438/93448 PROMs. Socket boards for the ultraviolet eraseable devices are also available. A cable to the Quad I/O Module and a power cord are also included in the basic unit.

Fairchild Fusible Link PROMS	Ultraviolet Eraseable PROMs
93436 (512 × 4)	2704 (512 × 8)
93446 (512 × 4)	2708 (1024 × 8)
93438 (512 × 8)	
93448 (512 × 8)	

©IC MASTER 1978

F3870 DEVELOPMENT SUPPORT



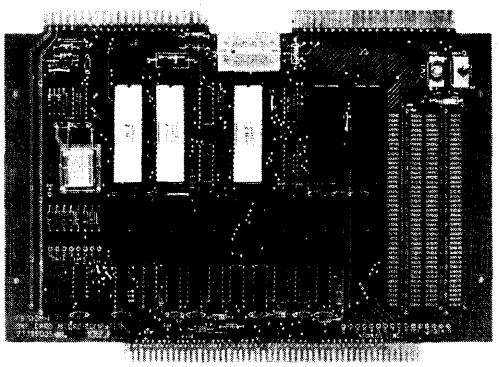
The F8 Formulator family of development equipment also supports the F3870, the one-chip microcomputer manufactured by Fairchild. The Formulator Operating System, utility program, and the Fairbug monitor are completely compatible with the F3870, since it shares the same instruction set with the Formulator. A Simulation (Quad I/O) Module and an In-Circuit Emulation (ICE) cable are available to extend the Formulator features to the user's prototype or production breadboard. This creates a powerful design tool for creating the user's own F3870 software. In addition, the F3870 Emulator, a single stand-alone module for emulating the final F3870 software in PROMs, is available for building prototype systems.

F3870 STIMULATION

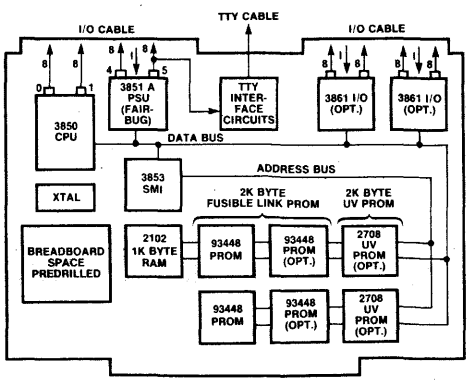
The non-microprocessor elements of the user's hardware configuration can be assembled on a breadboard and connected to Mark I, II, IIFD, III or IIIFD via the ICE cable plugged into a 40-pin socket on the user's board. The cable connector on the Processor Module in the Formulator provides I/O ports 0 and 1, while the Simulation (Quad I/O) Module provides I/O ports 4 and 5. This system provides real-world simulation of the user's components in their actual environment with the vital microprocessor signals, including the complete software debugging features of the Formulator, cabled to the external breadboard.

F3870 EMULATOR

After F3870 ROM codes are frozen, a smaller, easier-to-handle and less expensive tool is required. To accomplish this design-in task, Fairchild has developed the F3870 Emulator. The F3870 Emulator contains sockets for two 2708s or two 2716 EROMs in place of the F3870 on-chip ROM so ROM codes can be verified and easily changed. The F3870 Emulator plugs directly into the F3870 40-pin socket in the production prototype using a short Emulator cable. The printed circuit module is approximately 5″ by 7 ″.



OCM-1 ONE-CARD MICROCOMPUTER



The OCM-1 is a complete microcomputer system contained on a single printed circuit board and offering the following features:

- 64-byte scratch pad memory
- 1K-byte RAM
- 8K-byte ROM (1K supplied, sockets provided for balance)
- 4K-byte EPROM (sockets provided)
- 4K-byte PROM (sockets provided)
- Up to four programmable timers
- Up to four programmable interrupts
- RS232 interface (current loop optional)
- 2 MHz clock
- Self-contained Fairbug teletype operating system
- Up to 64 individually programmable, bidirectional, latched I/O lines.

The unit is based on the F8 microcomputer and is fully supported by the Formulator family of program development aids. In addition, the OCM-1 contains a built-in teletype operating system, called Fairbug I, contained in the F3851A Program Storage Unit. Using an OCM-1-to-TTY cable assembly, the board can be directly coupled to a teletype or RS232 terminal to display or alter memory location, to load and punch paper tape, or to make entries from the keyboard or by program instruction. An alternative built-in operating system, K-D Bug, contained in the F3856A PSU is also available. It provides all of the Fairbug I functions plus a resident monitor to facilitate operation with a low-cost calculator-style keyboard and LED display. A Fairbug user's guide is provided with the OCM-1. The K-D Bug should be ordered as a separate item.

OCM-1 Module

OCM-1 Block Diagram

©IC MASTER 1978

The OCM-1 processor section includes the 3850 Central Processing Unit, the F3853 Static Memory Interface, a 2 MHz clock, and reset circuitry.

The OCM-1 memory section contains the capability for the use of five different types of storage including 64 bytes of scratch pad, 1K bytes of RAM, sockets for 2K bytes of EROM (2708), sockets for 2K bytes of fusible link PROM (93448), and the Fairbug I operating system.

The I/O portion of the system is contained in the F3850 Central Processing Unit and a F3851A Program Storage Unit, each containing two 8-bit I/O ports. Two sockets are provided for inserting standard F8 PIO circuits (F3861 or F3871) or, if more ROM is required, standard PSUs (F3851 or F3856) may be inserted. In either case, four additional I/O ports are provided bringing the maximum total to eight I/O ports (64 lines). Only single-byte instructions are required to individually program these lines for either input or output functions. Latches on each line reduce external hardware cost. A circuit on the board gives the OCM-1 the capability of communicating with a teletype, RS232 device or 20mA current loop.

In its standard configuration, the OCM-1 contains two interrupts and two timers, one in the F3851A PSU and one in the F3853 SMI. Two additional interrupts and timers may be added by plugging the two additional PIOs into their sockets. A "daisy-chained" priority system determines which interrupt will be serviced if two or more requests are made simultaneously.

The OCM-1 requires three power supply voltages: +12 V @ 0.255 A, −5 V @ 0.4 A and −5 V @ 0.09 A. The −5V supply is used only for the 2708 EROM devices. All supply voltages are ± 5 % maximum.

The entire microcomputer is contained on a single board (epoxy glass with solder mask) measuring approximately 7.5 inches by 10.5 inches. It includes a 2-inch by 4-inch predrilled breadboarding area for users who want to develop unique system configurations. In addition, a Formulator-compatible 100-pin edge connector, a special connector for TTY or terminal, and two 44-pin edge connectors for F8 signals, are contained on the board. A switch to enable the Fairbug operating system is also provided. The OCM-1 is delivered completed with OCM-1 Users Manual, Fairbug Users Guide and F8 Guide to Programming.

FORMULATOR SUPPORT

In addition to the optional boards, peripherals, cables, and other accessories, the Mark I, Mark II, and Mark III Formulator systems are supported by a wide range of documentation, and an intensive training program.

FORMULATOR DOCUMENTATION

The Formulator user has access to a full range of reference and instructional manuals to aid him in his system design and programming.

F8 USER'S GUIDE

The F8 User's Guide is a detailed description of the F8 family of microprocessor devices. Microprocessor systems are discussed, with the configurations of the F8 circuits examined in depth. The User's Guide also outlines the F8 instruction set. Detailed specifications of each member of the F8 microprocessor family is given, including functional descriptions, logic diagrams, signal load levels, and timing diagrams for each circuit. Typical F8 system configurations are also presented.

GUIDE TO PROGRAMMING

The Guide to Programming is written for logic designers with little or no background in computer programming. It introduces machine and assembly language programming to the potential user of microprocessors and microcomputer systems. Introductory topics include flowcharting, memory allocation, source and object programs, and assembly language. More advanced topics include programmed /O, interrupts, programmable timers, subroutines, macros, data manipulation, and programmed direct memory access channels. Numerous examples of these programming techniques are given.

FORMULATOR USER'S GUIDE

The Formulator User's Guide fully describes the operation of the Formulator Development System. It covers the Mark I, Mark II, and Mark III hardware configurations and contains a detailed description of the Formulator software—the monitor, the editor, the assembler, and the debug program. The F8 DOS-III User's Guide is also available for Mark IIFD and Mark IIIFD systems.

FORMULATOR HARDWARE REFERENCE MANUAL

This book presents an in-depth technical description of the F8 Formulator System, its component subsystems, and options. The technical description includes general functional characteristics, theory of operation, and detailed description of interface signals.

F8 TRAINING CLASS

To help applications engineers start designing with the F8 microprocessor, Fairchild offers an intensive four-day training course. Lectures are presented dealing with F8 features, architecture, and programming. In laboratory sessions, students prepare and run small F8 programs using the Formulator development systems.

F8 AND MICROMACHINE SERIES

Versatile . . . Efficient . . . Inexpensive

THE F8 SERIES

The ultimate goal, from design concept through development and production, was to produce the most versatile, efficient, cost-effective microprocessor system available today. To accomplish this, five stringent parameters, based on user experience with other systems, were set forth as guidelines for the F8.

- **MINIMUM PARTS COUNT**
- **COST EFFECTIVENESS**
- **SIMPLE PERIPHERAL INTERFACES**
- **EASY EXPANSION THROUGH MODULAR ARCHITECTURE**
- **SIMPLIFIED PROGRAMMING AND DEBUGGING**

How Were These Goals Met?

By . . . *unique system partioning* the system functions have been divided amont the various circuits of the F8 family to provide sophisticated modularity. As a result, it is now possible to build a minimum microprocessor system with only two devices. To this system PSU, RAM and I/O devices can be added to form medium size or memory intensive systems, with a minimum of use of external parts. And, finally, for solving complex problems, the F8 devices can be connected as subsystems into a synergistic system of independent microprocessors.

By . . . *incorporating the I/O structure on the chips* so that the majority of the peripheral devices can be directly controlled without the need for special circuits. The trick is to accommodate the characteristics of a given peripheral device in the software. The I/O hardware structure includes a programmable timer, an efficient interrupt system and bidirectional I/O ports.

THE MICROMACHINE SERIES

The Micromachine series offers a single-chip solution for the cost sensitive microprocessor controller applications. The F3870 8-bit microcomputer is the first device in this series.

The Result?

A complete family of F8 and Micromachine circuits which cover the microprocessor spectrum from the most simple to the most complex.

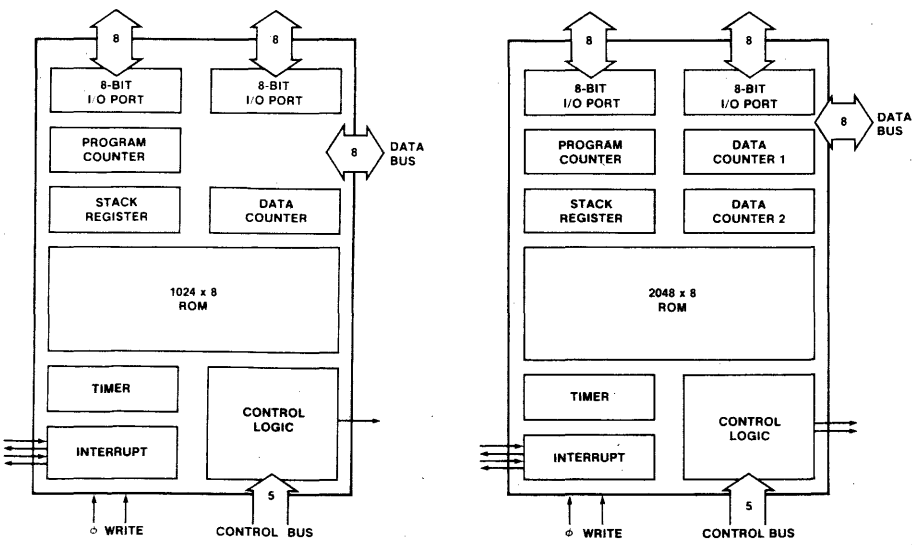
THE F8 SERIES

3850 Central Processing Unit (CPU)



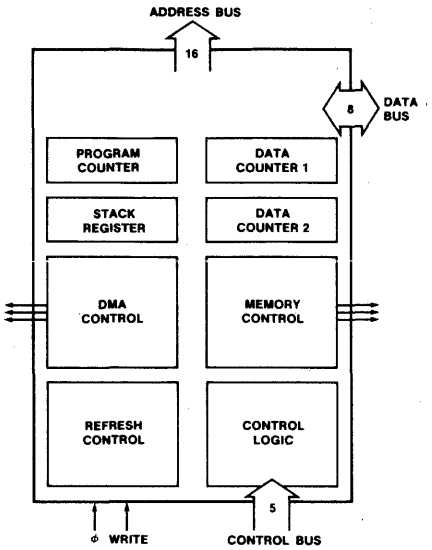
Fairchild's F8 CPU contains all of the functions needed to provide the most inexpensive solution to your design problems. The 3850 has 64 bytes of RAM, 16 I/O ports and a complete set of easy to understand instructions with both binary and decimal arithmetic operations.

3850
CPU BLOCK DIAGRAM

3851/3856 Program Storage Units (PSUs)

The 3851 PSU contains 1K of program storage and the 3856 2K. Both provide 16 bits of bi-directional I/O ports, a timer and external interrupt and a vectored, prioritized interrupt structure. Additional PSUs may be added as required and I/O expansion naturally follows. Each PSU may be considered a generalized peripheral controller.

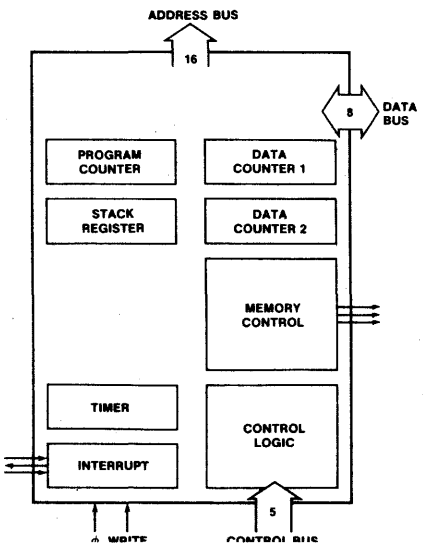
PSU BLOCK DIAGRAM



©IC MASTER 1978

3852/3853/3857 Memory Interface Circuits

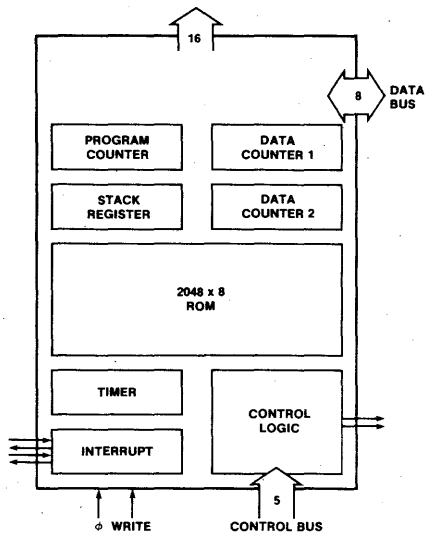
Additional memory can be easily added to the system by using any of the three Memory Interface Circuits. Each device generates the 16 address lines and signals necessary to interface with up to 65K bytes of RAM, PROM or ROM memory and they all may be used in conjunction with any standard semiconductor memory device.



The 3852 Dynamic Memory Interface (DMI) provides memory refresh and DMA logic which run transparent to the CPU without any degradation in the system throughput time.

3852
DMI BLOCK DIAGRAM

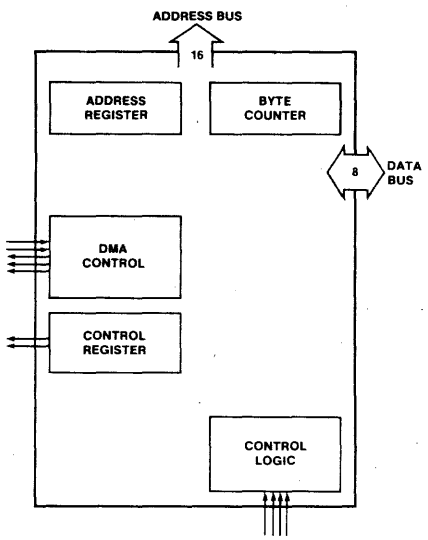
The 3853 Static Memory Interface (SMI) provides a programmable timer and external interrupt capability with a software loadable interrupt vector address in addition to the 16 address lines and memory control logic.



3853
SMI BLOCK DIAGRAM

©IC MASTER 1978

The 3857 Program Storage and Memory Interface (PSMI) provides 2K of ROM, an external interrupt and timer with masked interrupt vector as well as 16 address lines and memory control logic.

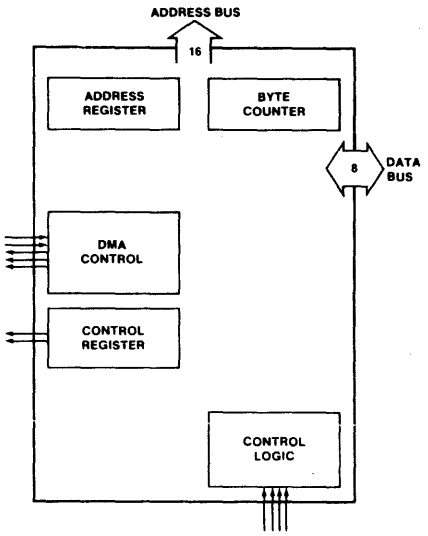


3857
PSMI BLOCK DIAGRAM

3854/3855 Direct Memory Access (DMA)

The DMA circuits provide a high-speed data path between a system memory and the peripheral electronics with up to 500 kilo bytes of transparent data transfer per second. These circuits can transfer data blocks of up to 4096 bytes and can interrupt the CPU when this data transfer is complete or can be programmed to continue transferring until stopped.

3854
DMA BLOCK DIAGRAM

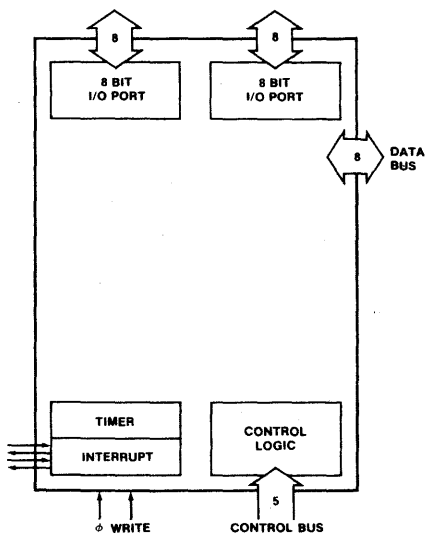


©IC MASTER 1978

The 3854, when working in conjunction with the 3852, does not require overhead electronics to track memory addresses, bytes transferred and handshaking signals.

The 3855 DMA is designed for use with other processors such as the Fairchild 6800 or the 8080 and Z80 circuits.

3855
DMA BLOCK DIAGRAM

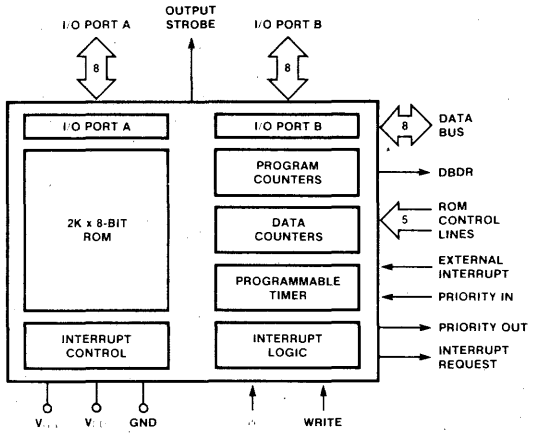


3861/3871 Peripheral Input/Output

The 3861 PIO circuit contains all of the logic of the 3851 PSU without the 1K ROM. The 3861 is available in five versions as listed below.

TYPE	I/O PORTS	INTERRUPT ADDRESS VECTOR	
		TIMER	EXTERNAL
A	4-7	0600	0680
B	8-13	0340	03C0
C	20-23	0320	03A0
D	24-27	0360	03E0
E	4-7	0020	00A0

3861
PIO BLOCK DIAGRAM

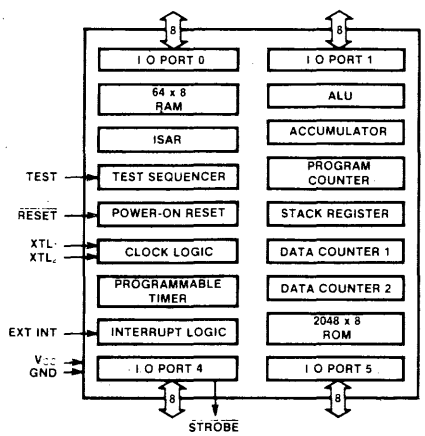


©IC MASTER 1978

The 3871 contains an improved timer and event counter identical to that used on the 3870. The 3871 is available in four versions as listed below.

TYPE	I/O PORTS	PORT TYPE	INTERRUPT ADDRESS VECTOR	
			TIMER	EXTERNAL
E	4-7	Standard	0020	00A0
F	4-7	Direct Drive	0020	00A0
G	4-7	Open Drain	0020	00A0
H	8-B	Standard	0420	04A0

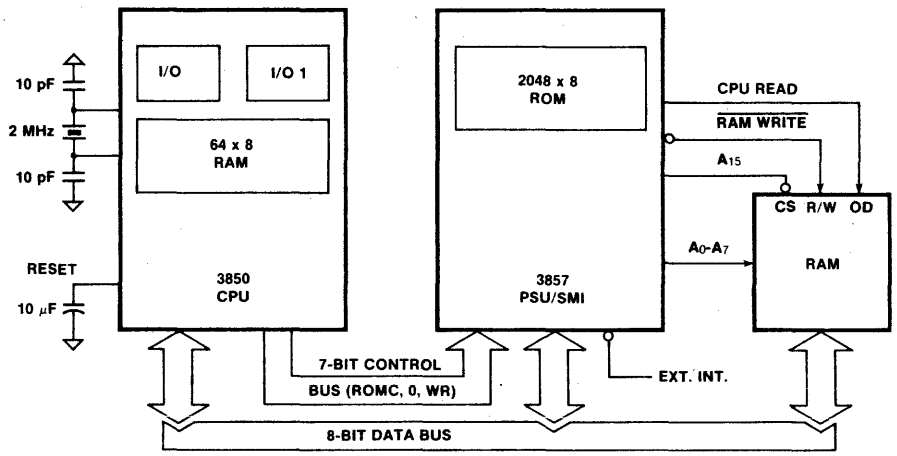
3871
PIO BLOCK DIAGRAM



THE MICROMACHINE SERIES

F3870 MicroMachine™2

The Fairchild MicroMachines are a series of single-chip microcomputer circuits to serve the high-volume cost-sensitive controller market. The F3870 MicroMachine 2 is the first offering in this series. The F3870 is a complete 8-bit microcomputer on a single MOS integrated circuit. The F3870 can execute the F8 instruction set of more than 70 commands, allowing expansion into multi-chip configurations with software compatibility. The device features 2048 bytes of ROM, 64 bytes of scratch-pad RAM, a programmable binary timer, 32 bits of I/O, and a single +5 Volt power supply requirement.



Utilizing ion-implanted, n-channel silicon-gate technology and advanced circuit design techniques, the single-chip F3870 offers maximum cost effectiveness in a wide range of control and logic replacement applications.

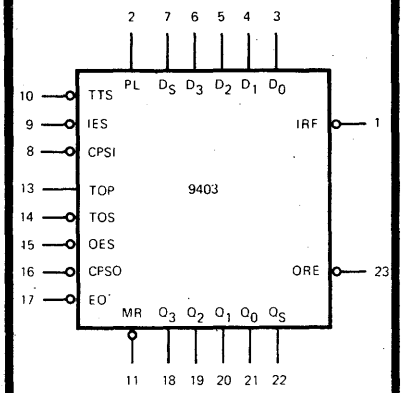
9403

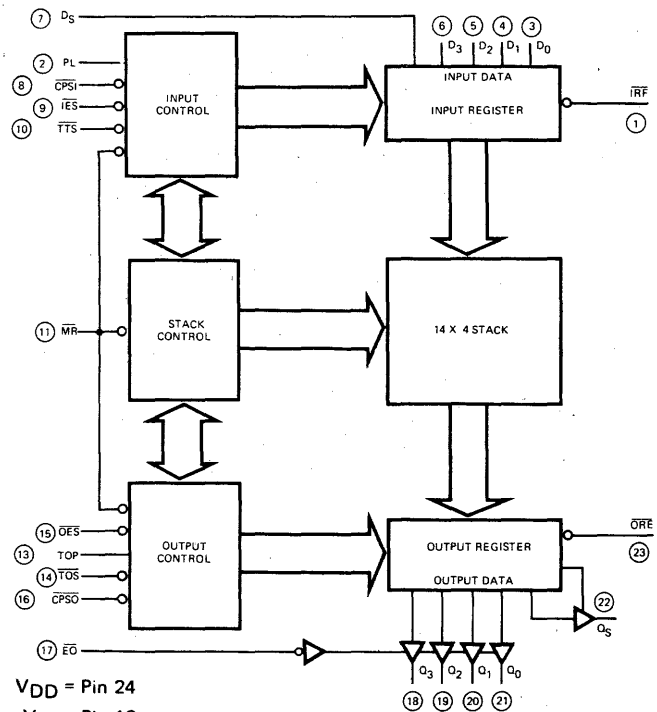
FIRST-IN FIRST-OUT (FIFO) BUFFER MEMORY



FAIRCHILD TTL MACROLOGIC

DESCRIPTION – The 9403 is an expandable fall-through type high-speed First-In First-Out (FIFO) Buffer Memory optimized for high speed disc or tape controllers and communication buffer applications. It is organized as 16 words by four bits and may be expanded to any number of words or any number of bits (in multiples of four). Data may be entered or extracted asynchronously in serial or parallel, allowing economical implementation of buffer memories.

The 9403 has 3-state outputs which provide added versatility and is fully compatible with all TTL families.



- **10 MHz SERIAL OR PARALLEL DATA RATE**
- **SERIAL OR PARALLEL INPUT**
- **SERIAL OR PARALLEL OUTPUT**
- **EXPANDABLE WITHOUT EXTERNAL LOGIC**
- **3-STATE OUTPUTS**
- **FULLY COMPATIBLE WITH ALL TTL FAMILIES**
- **SLIM 24-PIN PACKAGE**

LOGIC SYMBOL

Q_S	Serial Data Output	10 U.L.	10 U.L.	(Note b)
$\overline{IRF}$	Input Register Full Output	10 U.L.	5 U.L.	LOW when input register is full (Note b).
$\overline{ORE}$	Output Register Empty Output	10 U.L.	5 U.L.	HIGH when output register contains valid data.

NOTE: a. 1 Unit Load (U.L.) = 40 μA HIGH, 1.6 mA LOW.
b. Output fan-out with $V_{OL} \leq 0.5$ V.

FUNCTIONAL DESCRIPTION – As shown in the block diagram the 9403 consists of three sections:

1. An Input Register with parallel and serial data inputs as well as control inputs and outputs for input handshaking and expansion.
2. A 4-bit wide, 14-word deep fall-through stack with self-contained control logic.
3. An Output Register with parallel and serial data outputs as well as control inputs and outputs for output handshaking and expansion.

Since these three sections operate asynchronously and almost independently, they will be described separately below:

Input Register (Data Entry):
The Input Register can receive data in either bit-serial or in 4-bit parallel form. It stores this data until it is sent to the fall-through stack and generates the necessary status and control signals.

Figure 1 is a conceptual logic diagram of the input section. As described later, this 5-bit register is initialized by setting the F3 flip-flop and resetting the other flip-flops. The Q-output of the last flip-flop (FC) is brought out as the "Input Register Full" output ($\overline{IRF}$). After initialization this output is HIGH.

Parallel Entry – A HIGH on the PL input loads the $D_0 - D_3$ inputs into the $F_0 - F_3$ flip-flops and sets the FC flip-flop. This forces the $\overline{IRF}$ output LOW indicating that the input register is full. During parallel entry, the $\overline{CPSI}$ input must be LOW. If parallel expansion is not being implemented, $\overline{IES}$ must be LOW to establish row mastership (see Expansion section).

©IC MASTER 1978

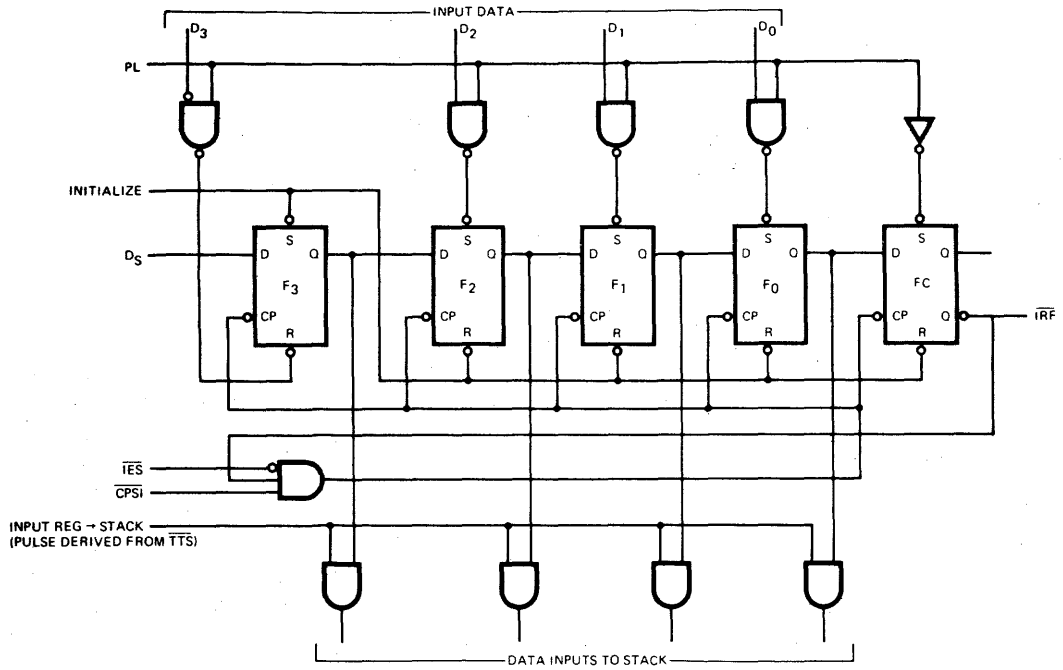

Fig. 1
CONCEPTUAL INPUT SECTION

Serial Entry – Data on the D_S input is serially entered into the F_3, F_2, F_1, F_0, FC shift register on each HIGH-to-LOW transition of the CPSI clock input, provided IES and PL are LOW.

After the fourth clock transition, the four data bits located in the four flip-flops F_0 – F_3. The FC flip-flop is set, forcing the $\overline{IRF}$ output LOW and internally inhibiting $\overline{CPSI}$ clock pulses from effecting the register. *Figure 2* illustrates the final positions in a 9403 resulting from a 64-bit serial bit train. B_0 is the first bit, B_{63} the last bit.

Transfer to the Stack –The outputs of Flip-Flops F_0 – F_3 feed the stack. A LOW level on the $\overline{TTS}$ input initiates a "fall-through" action. If the top location of the stack is empty, data is loaded into the stack and the input register is re-initialized. Note that this initialization is postponed until PL is LOW again. Thus, automatic FIFO action is achieved by connecting the $\overline{IRF}$ output to the $\overline{TTS}$ input.

An RS Flip-Flop (the Request Initialization Flip-Flop shown in *Figure 10*) in the control section records the fact that data has been transferred to the stack. This prevents multiple entry of the same word into the stack despite the fact the $\overline{IRF}$ and $\overline{TTS}$ may still be LOW. The Request Initialization Flip-Flop is not cleared until PL goes LOW. Once in the stack, data falls through the stack automatically, pausing only when it is necessary to wait for an empty next location. In the 9403, as in most modern FIFO designs, the $\overline{MR}$ input only initializes the stack control section and does not clear the data.

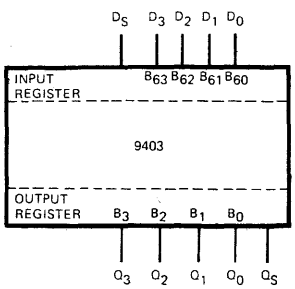

Fig. 2
FINAL POSITIONS IN A 9403 RESULTING FROM A 64-BIT SERIAL TRAIN

©IC MASTER 1978

Output Register (Data Extraction) – The Output Register receives 4-bit data words from the bottom stack location, stores it and outputs data on a 3-state 4-bit parallel data bus or on a 3-state serial data bus. The output section generates and receives the necessary status and control signals. *Figure 3* is a conceptual logic diagram of the output section.

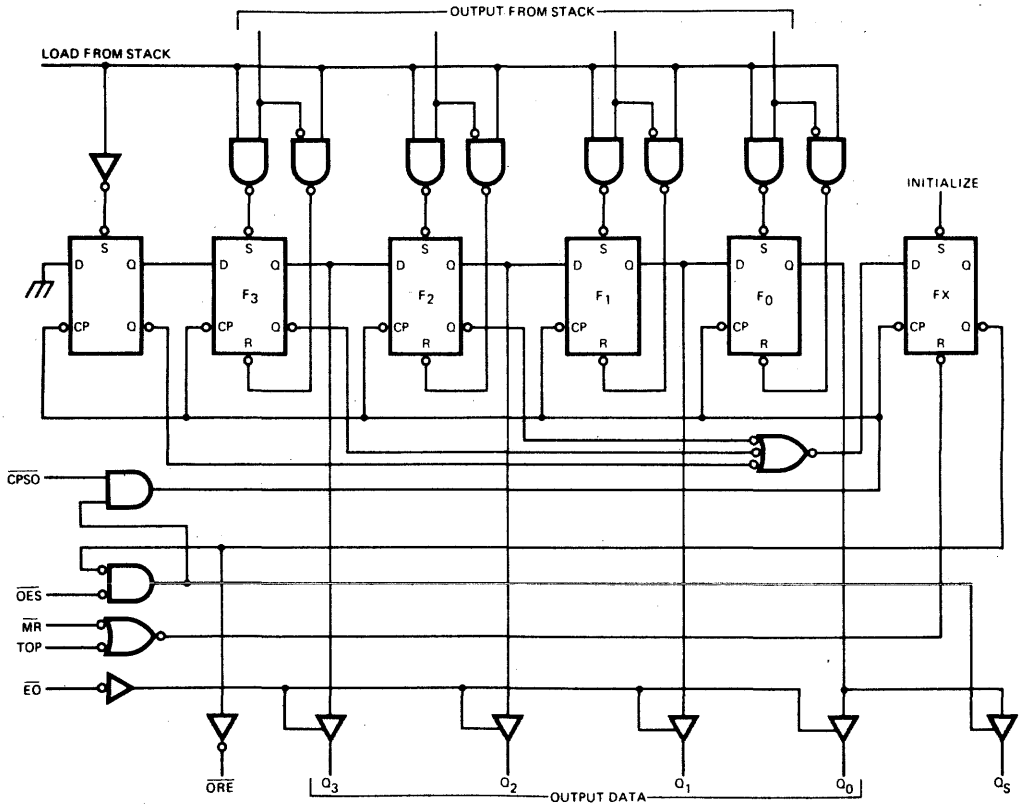

Fig. 3
CONCEPTUAL OUTPUT SECTION

Parallel Data Extraction – When the FIFO is empty after a LOW pulse is applied to $\overline{MR}$, the Output Register Empty ($\overline{ORE}$) output is LOW. After data has been entered into the FIFO and has fallen through to the bottom stack location, it is transferred into the Output Register provided the "Transfer Out Parallel" (TOP) input is HIGH. As a result of the data transfer $\overline{ORE}$ goes HIGH, indicating valid data on the data outputs (provided the 3-state buffer is enabled). TOP can now be used to clock out the next word. When TOP goes LOW, $\overline{ORE}$ will go LOW indicating that the output data has been extracted, but the data itself remains on the output bus until the next HIGH level at TOP permits the transfer of the next word (if available) into the Output Register. During parallel data extraction $\overline{CPSO}$ should be LOW. $\overline{TOS}$ should be grounded for single slice operation or connected to the appropriate $\overline{ORE}$ for expanded operation (see Expansion section).

TOP is not edge triggered. Therefore, if TOP goes HIGH before data is available from the stack, but data does become available before TOP goes LOW again, that data will be transferred into the Output Register. However, internal control circuitry prevents the same data from being transferred twice. If TOP goes HIGH and returns to LOW before data is available from the stack, ORE remains LOW indicating that there is no valid data at the outputs.

Serial Data Extraction – When the FIFO is empty after a LOW pulse is applied to $\overline{MR}$, the Output Register Empty ($\overline{ORE}$) output is LOW. After data has been entered into the FIFO and has fallen through to the bottom stack location, it is transferred into the Output Register provided $\overline{TOS}$ is LOW and TOP is HIGH. As a result of the data transfer $\overline{ORE}$ goes HIGH indicating valid data in the register. The 3-state Serial Data Output, Q_S, is automatically enabled and puts the first data bit on the output bus. Data is serially shifted out on the HIGH-to-LOW transition of $\overline{CPSO}$. To prevent false shifting, $\overline{CPSO}$ should be LOW when the new word is being loaded into the Output Register. The fourth transition empties the shift register, forces $\overline{ORE}$ output LOW and disables the serial output, Q_S (refer to *Figure 3*). For serial operation the $\overline{ORE}$ output may be tied to the $\overline{TOS}$ input, requesting a new word from the stack as soon as the previous one has been shifted out.

©IC MASTER 1978

Horizontal and Vertical Expansion - The 9403 can be expanded in both the horizontal and vertical directions without any external parts and without sacrificing any of its FIFO's flexibility for serial/parallel input and output. The interconnections necessary to form a 31-word by 16-bit FIFO are shown in *Figure 4.* Using the same technique, any FIFO of (15m + 1) words by (4n) bits can be constructed, where m is the number of devices in a column and n is the number of devices in a row. *Figures 5* and *6* show the timing diagrams for serial data entry and extraction for the 31-word by 16-bit FIFO shown in *Figure 4.* The final position of data after serial insertion of 496 bits into the FIFO array of *Figure 4* is shown in *Figure 7.*

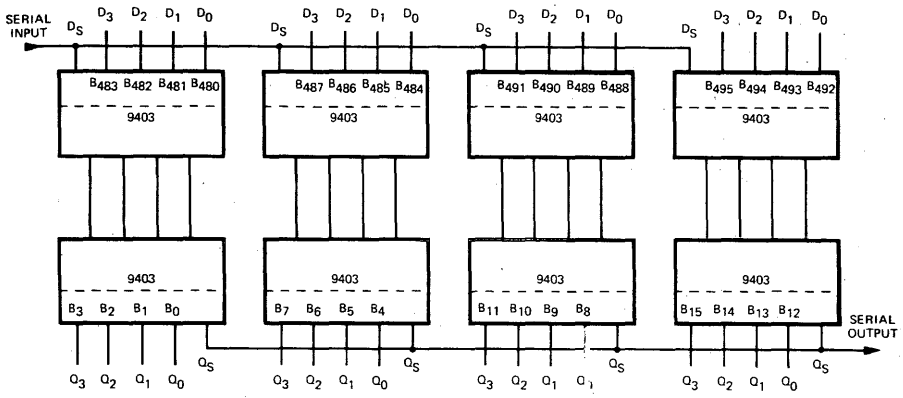

Fig. 7
FINAL POSITION OF A 496-BIT SERIAL INPUT

Interlocking Circuitry – Most conventional FIFO designs provide status signals analogous to $\overline{IRF}$ and $\overline{ORE}$. However, when these devices are operated in arrays, variations in unit to unit operating speed require external gating to assure all devices have completed an operation. The 9403 incorporates simple but effective "master/slave" interlocking circuitry to eliminate the need for external gating.

In the 9403 array of *Figure 4* devices 1 and 5 are defined as "row masters" and the other devices are slaves to the master in their row. No slave in a given row will initialize its Input Register until it has received LOW on its $\overline{IES}$ input from a row master or a slave of higher priority.

In a similar fashion, the $\overline{ORE}$ outputs of slaves will not go HIGH until their $\overline{OES}$ inputs have gone HIGH. This interlocking scheme ensures that new input data may be accepted by the array when the $\overline{IRF}$ output of the final slave in that row goes LOW and that output data for the array may be extracted when the $\overline{ORE}$ of the final slave in the output row goes HIGH.

The row master is established by connecting its $\overline{IES}$ input to ground while a slave receives its $\overline{IES}$ input from the $\overline{IRF}$ output of the next higher priority device. When an array of 9403 FIFOs is initialized with a LOW on the $\overline{MR}$ inputs of all devices, the $\overline{IRF}$ outputs of all devices will be HIGH. Thus, only the row master receives a LOW on the $\overline{IES}$ input during initialization. *Figure 8* is a conceptual logic diagram of the internal circuitry which determines master/slave operation. Whenever $\overline{MR}$ and $\overline{IES}$ are LOW, the Master Latch is set. Whenever $\overline{TTS}$ goes LOW the Request Initialization Flip-Flop will be set. If the Master Latch is HIGH, the Input Register will be immediately initialized and the Request Initialization Flip-Flop reset. If the Master Latch is reset, the Input Register is not initialized until $\overline{IES}$ goes LOW. In array operation, activating the $\overline{TTS}$ initiates a ripple input register initialization from the row master to the last slave.

A similar operation takes place for the output register. Either a $\overline{TOS}$ or TOP input initiates a load-from-stack operation and sets the ORE Request Flip-Flop. If the Master Latch is set, the last Output Register Flip-Flop is set and $\overline{ORE}$ goes HIGH. If the Master Latch is reset, the $\overline{ORE}$ output will be LOW until an $\overline{OES}$ input is received.

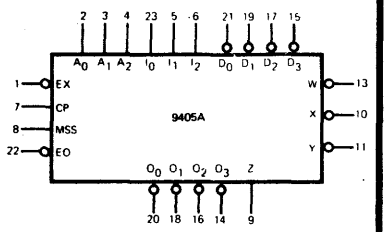
9405A

ARITHMETIC LOGIC REGISTER STACK

FAIRCHILD TTL MACROLOGIC

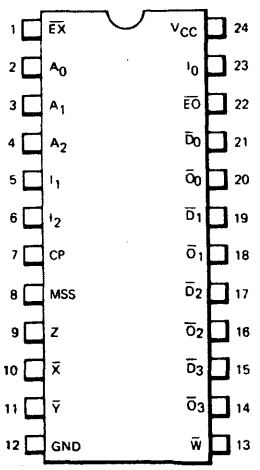
DESCRIPTION – The 9405A Arithmetic Logic Register Stack (ALRS) is designed to implement accumulators/general registers in high performance, microprogrammed digital systems (microprocessors). The 9405A is a 4-bit slice with expansion features for larger word lengths.



The device contains a 4-bit ALU, 8-word by 4-bit RAM, a 4-bit edge triggered output register and associated control logic. The ALU implements eight arithmetic and logic functions on two 4-bit operands. The desired function is specified by three instruction inputs (I-field). One of the operands is supplied from an external source (D-Bus). The second operand is supplied internally from one of the eight RAM locations. The desired RAM location is specified by the address inputs (A-field) when the clock input is HIGH. The result from the ALU is loaded into a RAM location during the period when the clock input is LOW. The address for the desired RAM location for writing is also specified by the A-field. Moreover, the result from the ALU is also loaded into the output register on LOW-to-HIGH transistion of the clock input. The output register provides the 4-bit output (O-Bus) through 3-state buffers.

For accumulator oriented microprocessor architectures, the A-field inputs to the 9405A remain the same during the HIGH and LOW period of the clock cycle. However, in general register oriented architectures, the A-field inputs are changed appropriately to realize the source and destination registers during HIGH and LOW period of the clock respectively.

Carry propagate and carry generate outputs are provided by the 9405A to facilitate carry lookahead expansion. The industry standard 93S42/74S182 carry lookahead unit can be used for this purpose. If high speed arithmetic is not needed, ripply carry expansion can be used. The ripple expansion eliminates the need for an external carry lookahead unit. The 9405A also provides four status signals (condition codes) to characterize the result of an operation – Zero, Negative, Overflow and Carry.



The 9405A is downward compatible with the 9405 and should be used in new designs. The 9405A is fully compatible with all TTL families.

MSS	Most Significant Slice Input (Active HIGH)	1.0 U.L.	0.23 U.L.
CP	Clock Input	1.0 U.L.	0.23 U.L.
$\overline{EO}$	Output Enable Input (Active LOW)	1.0 U.L.	0.23 U.L.
$\overline{EX}$	Execute Input (Active LOW)	1.0 U.L.	0.23 U.L.
$\overline{O}_0 - \overline{O}_3$	Data Outputs (Active LOW)	130 U.L.	10 U.L.
$\overline{W}$	Ripple Carry Output (Active LOW) (Note c)	10 U.L.	5.0 U.L.
$\overline{X}$	Carry Propagate Output (Note d)	10 U.L.	5.0 U.L.
$\overline{Y}$	Carry Generate Output (Note e)	10 U.L.	5.0 U.L.
Z	Zero Status Output (Active HIGH, Open Collector)(Note f)		5.0 U.L.

NOTES:
a) 1 Unit Load (U.L.) = 40 μA HIGH, 1.6 mA LOW (0.5 V).
b) I_0 used also for carry input.
c) W output also carries instruction information.
d) X output provides Negative status (active LOW) on most significant slice.
e) Y output provides Overflow status (active LOW) on most significant slice.
f) An external pull-up resistor is required to supply HIGH drive capability.

BLOCK DIAGRAM

©IC MASTER 1978

FUNCTIONAL DESCRIPTION – As shown in the block diagram, the 9405A consists of a 4-bit ALU, 8-word by 4-bit RAM with latches, an Instruction Decoder, control logic and a 4-bit Output Register.

The ALU receives the active LOW data ($\overline{D}_0$ – $\overline{D}_3$) as one operand while the RAM provides the second operand through its latches. The ALU output is fed as input to the RAM and the Output Register. The active LOW output bus ($\overline{O}_0$ – $\overline{O}_3$) is from the Output Register through 3-state buffers. A HIGH on the $\overline{EO}$ input disables the buffers (high impedance state) while a LOW enables them.

The 6-bit instruction input for the 9405A consists of two 3-bit fields: A-field and I-field. A_0 – A_2 specifies the operation to be performed. The 8-word RAM can be considered to be providing eight registers (R_0 – R_7) and eight different operations can be performed on these registers. The I-field inputs are decided by the Instruction Decoder to generate necessary control signals for the ALU. The ALU generates Carry (C), Carry Propagate (P), Carry Generate (G), Negative (N) and Overflow (V) signals to be used by the control logic. The control logic manipulates these signals as a function of the I-field inputs and an external control input signal MSS. The MSS input separates the most significant slice in an array of 9405As from the remaining slices. A HIGH on the MSS denotes the most significance (MSS input may be tied directly to V_{CC}). In general, all except the most significant 9405A will have a LOW on the MSS input. The control logic generates three user outputs, $\overline{W}$, $\overline{X}$ and $\overline{Y}$. The significance of these outputs is discussed under the Expansion section. The Zero output (Z) is provided by an open collector transistor.

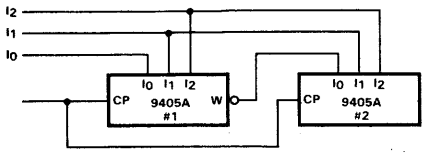
Table 1 lists the I-field assignment for the 9405A. There are only two arithmetic instructions in the table which require carry. It can also be noticed that the I_0 is the carry input. In the 9405A operation I_0 plays a dual role and will be discussed in the Expansion section.

The CP input is used to clock the 9405A. The content of the specified RAM location is read into the output latches whenever the CP input is HIGH. These latches are disabled when the CP is LOW. Thus, the information that was presented when CP was HIGH will be stored in the latches. Writing of the ALU result occurs whenever the CP and $\overline{EX}$ inputs are LOW. If the CP or $\overline{EX}$ input becomes HIGH, writing into the RAM will be terminated and the result will be loaded into the Output Register on the transition.

Operation – The 9405A can be used in two modes: general register and accumulator. In the general register mode, one address (R_X) is used to select a register (R_0 – R_7) for the source operand and another address (R_Y) is used to select a register (R_0 – R_7) as the destination for the result. This is accomplished by changing the A-field during the negative half cycle of the clock. In the accumulator mode, a single address is used to select a register (R_0 – R_7) for the source operand and the result is loaded back into the same register (implied destination). This mode is achieved by keeping the A-field unchanged for the entire clock cycle. The following page describes these modes in more detail.

TABLE 1
INSTRUCTION FIELD ASSIGNMENT

I_2	I_1	I_0	ACCUMULATOR MODE ($R_x = R_y$)		GENERAL REGISTER MODE ($R_x \neq R_y$)	
L	L	L	R_x *plus* $\overline{\text{D-Bus}}$ *plus* 1 → R_x	Accumulate and Increment	R_x *plus* $\overline{\text{D-Bus}}$ *plus* 1 → R_y	Add with Carry
L	L	H	R_x *plus* $\overline{\text{D-Bus}}$ → R_x	Accumulate	R_x *plus* $\overline{\text{D-Bus}}$ → R_y	Add
L	H	L	$R_x \cdot \overline{\text{D-Bus}}$ → R_x	Logical AND	$R_x \cdot \overline{\text{D-Bus}}$ → R_y	Logical AND
L	H	H	$\overline{\text{D-Bus}}$ → R_x	Load	$\overline{\text{D-Bus}}$ → R_y	Load
H	L	L	R_x → Output Register	Read	R_x → R_y	Transfer
H	L	H	$R_x + \overline{\text{D-Bus}}$ → R_x	Logical OR	$R_x + \overline{\text{D-Bus}}$ → R_y	Logical OR
H	H	L	$R_x \oplus \overline{\text{D-Bus}}$ → R_x	Exclusive OR	$R_x \oplus \overline{\text{D-Bus}}$ → R_y	Exclusive OR
H	H	H	D-Bus → R_x	Load Complement	D-Bus → R_y	Load Complement



NOTES:
1. R_x is the RAM location addressed by A_0 – A_2 when CP is HIGH.
2. R_y is the RAM location addressed by A_0 – A_2 when CP is LOW.
3. The result of any operation is always loaded into the Output Register at the end of the cycle provided that $\overline{EX}$ is LOW.

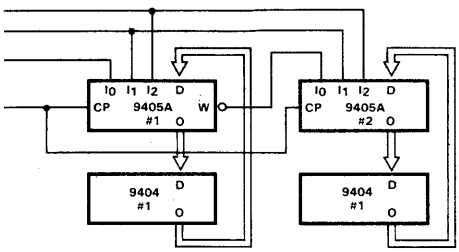
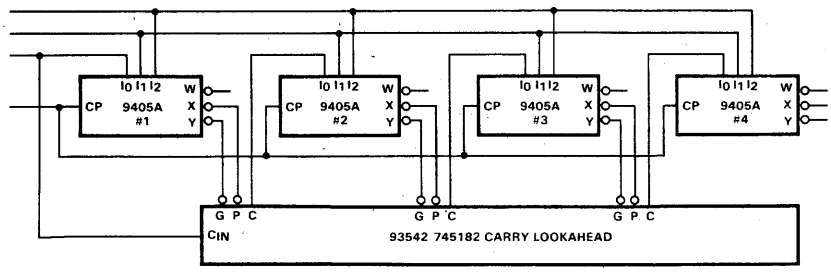
AC CHARACTERISTICS: MULTIPLE SLICE OPERATION



A single 9405A slice operating without overhead is guaranteed to operate at 13.3 MHz (75 ns). Such a configuration, however, would be extremely rare. AC guarantees for multiple slice operation depend on the configuration actually used. Several examples follow.

8-bit Machine with Ripple Carry

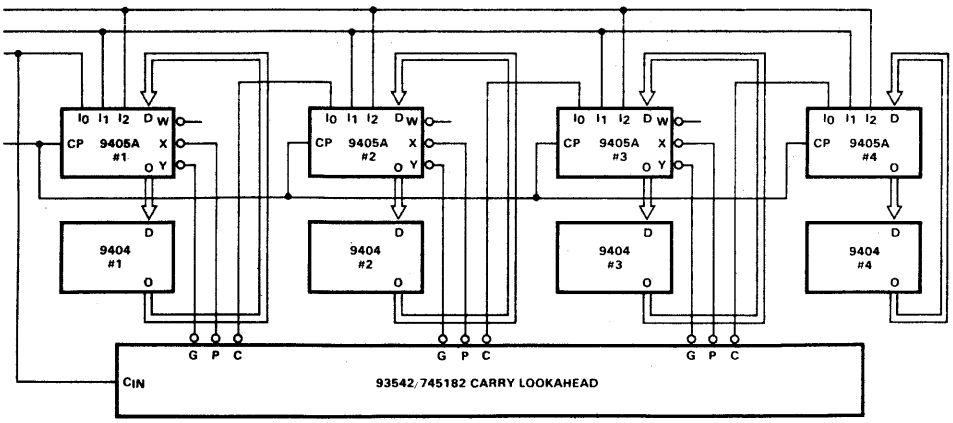


DESCRIPTION	TYP	MAX
Assume that at time, t = 0, the clock goes HIGH and the instruction and address information appear at the 9405A inputs		
t_{pd}-Address to $\overline{W}$ of 9405A # 1 ($\overline{W}$ is the carry-out pin)	44 ns	60 ns
t_{pd}-9405A # 2, I_0 to Status Flags (See Note 1)	30 ns	40 ns
Total clock period required	74 ns	100 ns
Frequency	13.5 MHz	10 MHz

8-bit Machine with Ripple Carry and DPS in Data Path (Note 2)

DESCRIPTION	TYP	MAX
Assume that at time, t = 0, the clock goes HIGH and the instruction and address information appear at the 9404 and 9405A inputs		
t_{pd}-Rising edge of clock to $\overline{O}$ outputs of 9405A # 1	18 ns	25 ns
t_{pd}-9404 # 1, $\overline{D}$ inputs to 9404 #1, O outputs (See 9404 data sheet)	15 ns	25 ns
t_{pd}-9405A # 1, $\overline{D}$ inputs to $\overline{W}$ ($\overline{W}$ is the carry-out pin)	30 ns	40 ns
t_{pd}-9405A # 2, I_0 to Status Flags (See Note 1)	30 ns	40 ns
Total clock period required	93 ns	130 ns
Frequency	10.7 MHz	7.7 MHz

16-bit Machine with Carry Lookahead



DESCRIPTION	TYP	MAX
Assume that at time, t = 0, the clock goes HIGH and the instruction and address information appear at the 9404 and 9405A inputs		
t_{pd}-Address inputs to $\overline{X}$, $\overline{Y}$ outputs of 9405A # 1	42 ns	58 ns
t_{pd}-G and P inputs of carry lookahead (Note: All G and P outputs are generated simultaneously. Therefore, 9405A # 2, # 3, # 4 set-up simultaneously.)	5 ns	7 ns
t_{pd}-9405A # 4, I_0 to Status Flags (See Note 1)	30 ns	40 ns
Total clock period required	77 ns	105 ns
Frequency	13 MHz	9.5 MHz

Notes on following pages.

©IC MASTER 1978

16-bit Machine with Carry Lookahead and DPS in Data Path (Note 3)

DESCRIPTION	TYP	MAX
Assume that at t = 0, the clock goes HIGH and the instruction and address information appear at the 9404 and 9405A inputs.		
t_{pd}-Rising edge of clock to $\overline{O}$ output of 9405A # 1	18 ns	25 ns
t_{pd}-9404 # 1, $\overline{D}$ inputs to $\overline{O}$ outputs	15 ns	25 ns
t_{pd}-9405A # 1, $\overline{D}$ inputs to $\overline{X}$, $\overline{Y}$ outputs (X, Y are carry propagate and generate)	30 ns	40 ns
t_{pd}-Carry propagate and generate inputs of carry lookahead to carry out. (Note that all carry outs are generated simultaneously.)	5 ns	7 ns
t_{pd}-9405A # 4, I_0 to Status Flags (See Note 1)	30 ns	40 ns
Total clock period required	98 ns	137 ns
Frequency	10 MHz	7.3 MHz

Architectures with Finite Delay between Rising Clock and the Appearance of Instructions and Address Information

Consider the previous case (16-bit with carry lookahead and DPS). After the clock rises, 25 ns is required before data appears at the input of the 9404. During this 25 ns there is no need for instruction or address information. Therefore, so long as the address and instructions appear within this 25 ns, no time is lost. Consequently, a pipeline system where the propagation delay of the pipeline register is less than 25 ns will operate at the speed guaranteed for the data path alone; *i.e.*, 7.3 MHz guaranteed for a 16-bit machine employing carry lookahead, 9404s in the data path, and a pipeline register with propagation delay less than 25 ns.

NOTES:
1. The 9405s could actually respond to a rising clock after the 18 ns (the I_0 to rising clock set-up time max). However, the status flags are not available until 40 ns have elapsed.
2. In this configuration, carry out for 9405A # 1 cannot be generated until the D inputs are present. These originate from the 9405A # 1 output register and must pass through 9404 # 1 before reaching the 9405A # 1 inputs.
3. In this configuration, carry propagate and generate outputs from 9405A # 1 cannot be generated until the D inputs are present. These originate from 9405A # 1 outputs register and must pass through 9404 # 1 before reaching the 9405A # 1 inputs.

Fairchild cannot assume responsibility for use of any circuitry described other than circuitry entirely embodied in a Fairchild product. No other circuit patent licenses are implied.

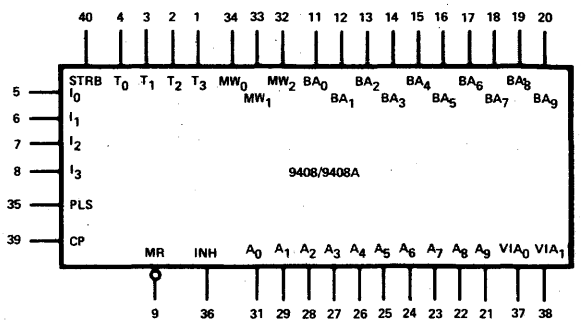
9408/9408A

MICROPROGRAM SEQUENCER

FAIRCHILD I^3L^{TM} MACROLOGIC

DESCRIPTION – The 9408/A Microprogram Sequencers control the order in which microinstructions are fetched from the control memory. It contains a 10-bit program counter, a 4-level last-in first-out stack and associated control logic. It can control up to a maximum of 1024 words of memory. For larger word capacities external paging can be used. The 9408/A are controlled by a 4-bit instruction input. The instruction set includes Fetch, Conditional and Unconditional Branches, Branch to Subroutine and Return from Subroutine.



There are seven test inputs – four participate in conditional branches, and three in multiway branches. The conditional test lines are flip-flop buffered. These flip-flops can be tested individually by appropriate branch instructions. The three multiway test inputs are used to form the least significant three bits of the branch address for a multiway branch. Thus, branching occurs at one of eight unique locations depending on the bit pattern present on these three inputs.

The 9408/A are designed to operate in pipeline or non-pipeline mode as desired by the user. The device operates synchronously with the clock input and can be initialized using the Master Reset input.

The 9408/A are fabricated using Integrated Injection Logic (I^3L^{TM}) technology and fully compatiable with all TTL families.

FUNCTIONAL DESCRIPTION – The 9408/A Microprogram Sequencers, shown in the block diagram consists of a 10-bit Program Counter (PC), a 4-word by 10-bit Last-In First-Out (LIFO) Stack with associated control, an Input Multiplexer, a Pipeline Multiplexer, an Instruction Decoder, a 10-bit Incrementer, and a 4-bit Test Register comprised of four edge-triggered D flip-flops.

The Pipeline Multiplexer has two ports – the PC output provides the input port for the non-pipeline mode and the Input Multiplexer output provides the input port for the pipeline mode. Port selection is controlled by the Pipeline Select (PLS) and Master Reset (MR) inputs. A LOW level on the MR input forces the non-pipeline mode of operation and clears the PC. Thus when the 9408/A are initialized by the MR input the A_0 through A_9 outputs are LOW regardless of the state of the PLS input. A LOW on the PLS input specifies non-pipeline mode and a HIGH specifies pipeline mode.

The Program Counter is a 10-bit edge-triggered register. The LOW-to-HIGH transition on the Clock (CP) input loads the Input Multiplexer output into the PC. Because of the edge-triggered nature of the PC register, the PC output remains static for a full clock cycle. Thus, in the non-pipeline mode, the PC output can be used to address a control memory built with static devices without storing the memory output in an external microinstruction register. However, in the pipeline mode, the 9408/A provide the next address information as soon as available; therefore, execution of a microinstruction can be overlapped with the fetching of the next microinstruction. To ensure microinstruction stability for a full clock cycle, the control-memory output should be buffered with an external microinstruction register.

The Input Multiplexer receives data from four different sources. One port is the output of the LIFO Stack; a second is the output of the 10-bit Incrementer. The Incrementer always adds one to the PC contents. The third and fourth ports are the branch and multiway-branch ports, the latter comprised of the seven most significant Branch Address inputs (BA_3 through BA_9) and the three Multiway inputs, (MW_0 through MW_2).

The 4-word by 10-bit LIFO Stack is a RAM and receives data from the Incrementer output. The stack control logic generates the appropriate control signals, while stack pointers in the Stack Control generate the read and write addresses.

The 4-bit Test Register consists of four type-D flip-flops. The data inputs, which are the four Test inputs (T_0 through T_3) are loaded on the LOW-to-HIGH transition of the Strobe input (STRB).

The Instruction Decoder receives the 4-bit Instruction input (I_0 through I_3) and the Test Register output and generates VIA_0, VIA_1 and Inhibit (INH) outputs of the 9408/A. In addition, it generates appropriate logic signals for the Stack Control and Input Multiplexer.

Stack Control – The 9408/A have a 4-level subroutine nesting capability as detailed in *Figure 1*. The R_0 and R_1 (Read Address) inputs to the 4-word by 10-bit LIFO Stack specify the address from which information will be read. The W_0 and W_1 (Write Address) inputs specify the address into which information will be written; and the 9408/A Increment output provides the information to be written into the stack (see block diagram). In addition, writing into the memory is controlled by the Write Enable ($\overline{WE}$) and $\overline{CP}$ inputs.

The R_0, R_1 and W_0, W_1 inputs of the LIFO Stack are derived from the outputs of a 3-bit edge-tirggered register called the Stack Pointer (SP). The least significant two bits (SP_0 and SP_1) of this register are the read address inputs to the memory. The SP outputs are also connected to a Stack-Pointer Incrementer and a Decrementer that generate SP + 1 and SP – 1 respectively. The least significant two bits of the Incrementer are the write address bits for the memory.

The outputs of the Incrementer, Decrementer and the Stack Pointer are fed as inputs to a 3-port Stack-Pointer Multiplexer which, in turn, feeds the Stack Pointer inputs. Stack pointer loading always occurs on the LOW-to-HIGH transition of the $\overline{CP}$ input. The $\overline{MR}$ input clears the Stack Pointer. The stack Pointer Control receives two inputs from the 9408/A instruction Decoder – the BSR input, which is active whenever a Branch-to-Subroutine (BSR) instruction is present on the I_0 through I_3 inputs, and the RTS input, which is active whenever a Return-from-Subroutine (RTS) instruction is specified. The port selection of the Stack Pointer Multiplexer is controlled by the outputs of the Stack Pointer Control. For all 9408/A instructions except BSR and RTS, the Stack Pointer Multiplexer selects the Stack Pointer outputs as the instruction source.

Writing into the memory takes place whenever the $\overline{WE}$ and $\overline{CP}$ inputs are LOW. Note that the most significant register bit, SP_2, controls the $\overline{WE}$ input to prevent writing into the memory when all four locations are filled with return addresses. Thus the 9408/A do not store and return addresses beyond four nesting levels.

©IC MASTER 1978

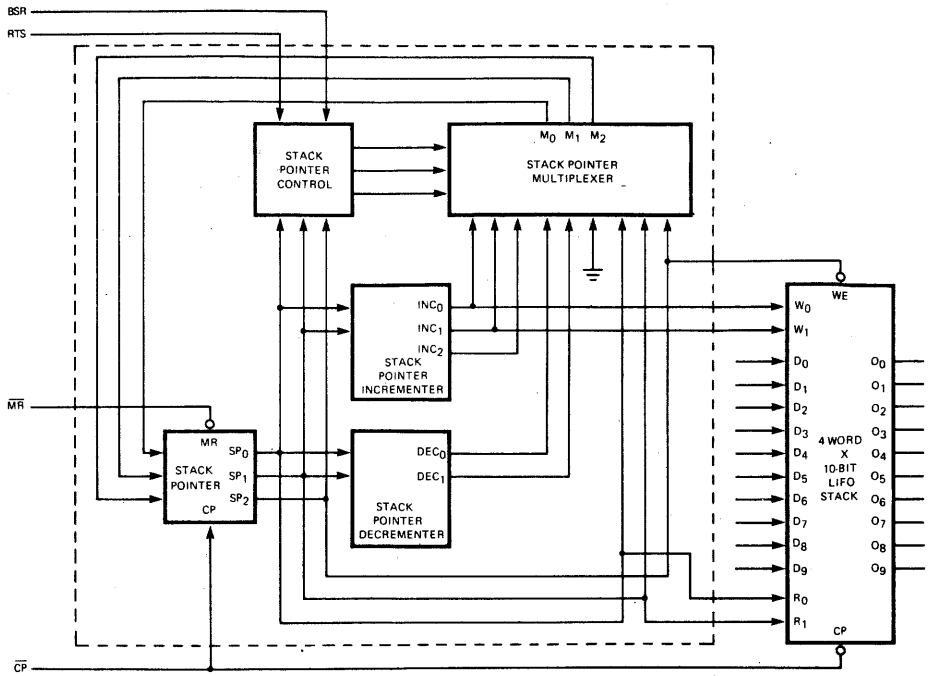

Fig. 1
STACK CONTROL

9408/A INSTRUCTIONS

The 9408/A instruction set have 16 instructions (*Table 1*). These instructions can be divided into three groups – unconditional branches, conditional branches and miscellaneous – and are specified by appropriate logic levels on the $I_0 - I_3$ inputs.

The unconditional branch group consists of four Branch VIA instructions ($BRV_0 - BRV_3$), Branch Multiway (BMW) and Branch to Subroutine (BSR). This group requires that the next address be explicitly specified on the BA inputs.

The conditional branch group consists of eight instructions, Branch Test HIGH ($BTH_0 - BTH_3$) and Branch Test LOW ($BTL_0 - BTL_3$), for interrogating the four test flip-flops of the 9408/A individually. The $BTH_0 - BTH_3$ instructions test flip-flops $T_0 - T_3$ respectively for a HIGH on the Q output (see block diagram). Similarly $BTL_0 - BTL_3$ test for a LOW on the corresponding Q input. If the test condition is satisfied, the next address is taken from the Branch ($BA_0 - BA_9$) inputs. If the test condition is not satisfied the 9408/A perform a Fetch operation.

The miscellaneous group consists of two instructions – Fetch (FTCH) and Return from Subroutine (RTS). These instructions do not require explicit specification of the next address. For the FTCH instruction, the next address is assumed to be the address of the current microinstruction + 1. For RTS, the next address is taken from the Stack. *The Inhibit (INH) outputs of the 9408/A are LOW only for FTCH and RTS instructions. For all other instructions, the INH output is HIGH.*

The VIA outputs of the 9408/A (VIA_0, VIA_1) are LOW for all instructions except $BRV_1 - BRV_3$. For BRV_1, the VIA_0 is HIGH and VIA_1 LOW. For BRV_2, the VIA_0 is LOW and VIA_1 HIGH. For BRV_3, both VIA_0 and VIA_1 are HIGH.

Unconditional Branches

$BRV_0 - BRV_3$ – Whenever a Branch VIA instruction code is present on the $I_0 - I_3$ inputs, the Instruction Decoder (see block diagram) establishes the appropriate HIGH/LOW pattern on the VIA_0 and VIA_1 outputs per *Table 1*. The Instruction Decoder also forces the INH output HIGH. Moreover, the $BA_0 - BA_9$ inputs are selected as the source of the next address by the Input Multiplexer.

If the 9408/A are in the pipeline mode (PLS input HIGH), the Pipeline Multiplexer transfers the $BA_0 - BA_9$ inputs to the $A_0 - A_9$ outputs. The $BA_0 - BA_9$ inputs are loaded into the PC on the LOW-to-HIGH transition of the CP input. On the other hand, if the non-pipeline mode of operation is selected, the $BA_0 - BA_9$ inputs appear on the output only after the LOW-to-HIGH transition of the CP input.

BMW – For a Branch Multiway instruction, the Instruction Decoder forces the VIA_0 and VIA_1 outputs LOW and INH output HIGH. The Input Multiplexer selects the $BA_3 - BA_9$ inputs as the most significant seven bits and $MW_0 - MW_2$ inputs as the least significant three bits of the next address. If the pipeline mode of operation is selected, the next address formed by the Input Multiplexer ($BA_3 - BA_9$ and $MW_0 - MW_2$ inputs) is transferred to the $A_0 - A_9$ outputs. On the LOW-to-HIGH transition of the CP input, this next address is also leaded into the PC. For non-pipeline mode, the next address is available on the $A_0 - A_9$ output only after the CP transition.

©IC MASTER 1978

BSR – During a Branch-to-Subroutine instruction, the Instruction Decoder forces a LOW on the VIA_0 and VIA_1 outputs and a HIGH on the INH output. The Input Multiplexer selects the BA_0 – BA_9 inputs as the source for the next address. If the pipeline mode is selected, this next address is transferred to the A_0 – A_9 outputs by the Pipeline Multiplexer. As usual, the PC is updated with this next address on the LOW-to-HIGH transition of the CP input. During non-pipeline operation, the next address appears on the output only after the CP transition.

The PC holds the address of the current microinstruction. For the BSR instruction, the return address must be stored in the Stack, which is fed by the PC through an Incrementer (see block diagram). When the CP input is LOW, the incremented value is written into the Stack as a return address. The LOW-to-HIGH transition of the CP input not only loads the PC with the next address, *i.e.*, BA_0 – BA_9 inputs, but also increments the Stack Pointer as explained above.

Conditional Branches

BTH_0 – BTH_3 – For a Branch Test HIGH instruction, the Instruction Decoder establishes a LOW on VIA_0 and VIA_1 outputs and HIGH on the INH output. It then tests for a HIGH on the Q output of the corresponding flip-flop in the test register. If a HIGH level is found, the Input Multiplexer selects the BA_0 – BA_9 inputs as the source for the next address.

On the other hand, if the tested Q output of the flip-flop is LOW, the Incrementer output is selected as the source of the next address by the Input Multiplexer. In either case, the PC is loaded with the next address on the LOW-to-HIGH transition of the CP input. As usual, if the pipeline mode is selected, the next address is transferred to the A_0 – A_9 outputs. For non-pipeline mode, the next address appears on the output after the clock transition.

BTL_0 – BTL_3 – Operation of the Branch Test LOW instructions is identical to BTH_0 – BTH_3 except that Q outputs of the test register flip-flops are tested for a LOW. If the tested output is LOW, a branch occurs. If tested output is HIGH the Incrementer output is the next address.

Miscellaneous

FTCH – For a Fetch instruction, the Instruction Decoder establishes a LOW on the VIA_0 and VIA_1 outputs. In addition, the INH output is also LOW. The Input Multiplexer selects the Incrementer output as the next address. If pipeline mode is selected, the Incrementer output is transferred to the A_0 – A_9 outputs. For non-pipeline mode, the incremented address appears at the output only after the clock transition.

RTS – For a Return-from-Subroutine instruction, the Instruction Decoder establishes a LOW on the VIA_0, VIA_1 and the INH outputs. The Input Multiplexer selects the Stack output as the source of the next address. As usual, for the pipeline mode, the next address is transferred to the output by the Pipeline Multiplexer. For non-pipeline operation, the next address appears on the output only after the clock transition. In addition, this instruction also decrements the Stack Pointer as described above.

DC CHARACTERISTICS: (Over Operating Temperature Range unless otherwise noted)

NOTES:
1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable device type.
2. Typical limits are at V_{CC} = 5.0 V, T_A = 25°C.
3. Not more than one output should be shorted at a time.

HM-6100

Low Power CMOS 12-Bit Microprocessor

Features

DESIGN

- Silicon Gate Complementary MOS
- Fully Static-0 to 8 MHz
- Single Power Supply
  - HM-6100/6100C V_{CC} = 5 volts
  - HM-6100A V_{CC} = 10 volts
- Crystal Controlled On Chip Timing
- Low Power Dissipation <10mW @ 4MHz @ 5 volts
- Wide Power Supply $4V \leq V_{CC} \leq 11V$
- TTL Compatible at 5 volts
- Excellent Noise Immunity
- -55°C to +125°C Operation

ARCHITECTURAL

- Executes PDP-8/E, Instruction Set
- Direct, Indirect, and Autoindexed Memory Addressing
- 12-Bit Memory Accumulator ADD Instruction
  - HM-6100 5 μsec @ +5 volts/4.0 MHz
  - HM-6100A 2.5 μsec @ +10 volts/8.0 MHz
  - HM-6100C 6 μsec @ +5 volts/3.3 MHz
- Input-Output Instruction
  - HM-6100 8.5 μsec @ +5 volts/4.0 MHz
  - HM-6100A 4.25 μsec @ +10 volts/8 MHz
  - HM-6100C 10.2 μsec @ +5 volts/3.3 MHz
- Single-Clock, Single-Instruction Capability
- Direct Memory Access (DMA)
- Interrupt
- Dedicated Control Panel Features

INTERFACE

- Memory – Any Speed, by Using WAIT Line
- Control Panel
- Switch Register
- Asynchronous CPU – Memory and CPU – Device Communication
- 63 I/O Devices with PDP-8/E Compatible Interface
- Device Controlled Input-Output
- All Control Signals Produced by the CPU

Applications

- Intelligent Computer Terminals
- POS Terminals
- Portable Terminals
- Aerospace/Satellite Systems
- Automotive Systems
- Remote Data Acquisition Systems
- Process Control
- Instrumentation
- Medical Electronics
- Displays
- Traffic Control
- Navigation

Description

The HM-6100 is a single address, fixed word length, parallel transfer microprocessor using 12-bit, two's complement arithmetic. The processors recognize the instruction set of Digital Equipment Corporation's PDP8/E minicomputer. The internal circuitry is completely static and is designed to operate at any speed between DC and the maximum operating frequency. Two pins are available to allow for an external crystal thereby eliminating the need for clock generators and level translators. The crystal can be removed and the processor clocked by an external clock generator. A 12-bit memory-accumulator ADD instruction, using a +5 volt supply, is performed in 5 μsec by the HM-6100, in 6 μsec by the HM-6100C and in 2.5 μsec by the HM-6100A using a +10 volt supply. The device design is optimized to minimize the number of external components required for interfacing with standard memory and peripheral devices.

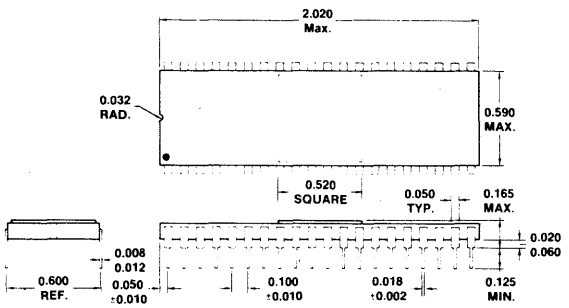
HD-6402



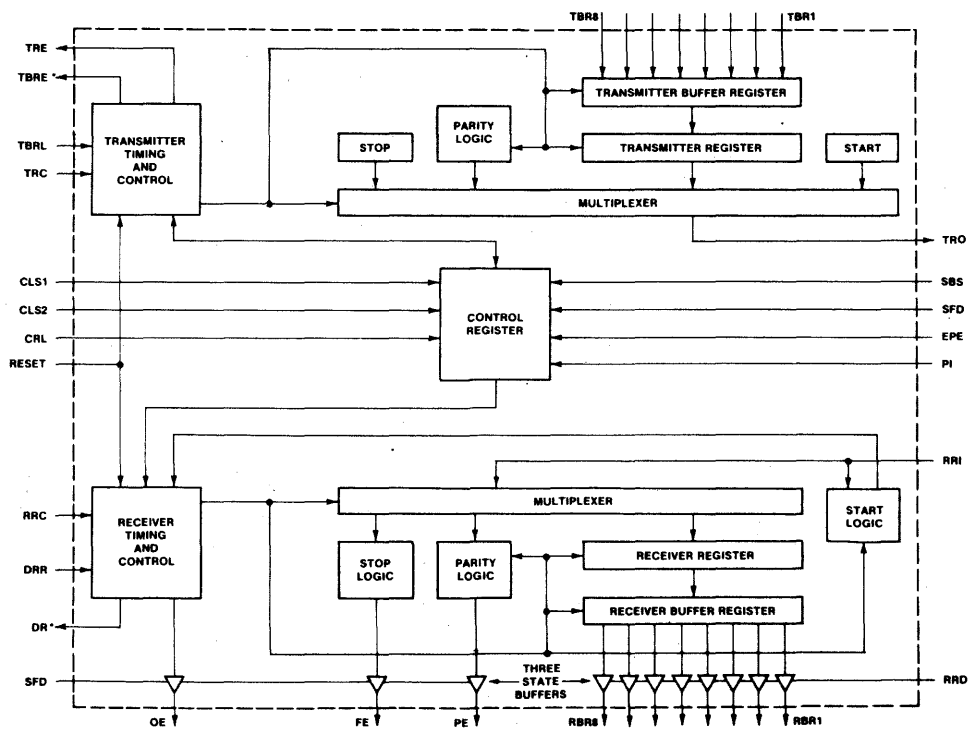
CMOS/LSI Universal Asynchronous Receiver (UART)

Features

- OPERATION FROM D.C. TO 2.0MHz
- LOW POWER – TYP 5mW @ 2.0MHz
- 4V – 11V OPERATION
- PROGRAMMABLE WORD LENGTH, STOP BITS AND PARITY
- AUTOMATIC DATA FORMATTING AND STATUS GENERATION
- COMPATIBLE WITH INDUSTRY STANDARD UARTs
- SINGLE POWER SUPPLY

Package

40 PIN D.I.P.



Description

The HD-6402 is a CMOS/LSI subsystem for interfacing computers or microprocessors to an asynchronous serial data channel. The receiver converts serial start, data, parity and stop bits to parallel data, verifying proper code transmission, parity, and stop bits. The transmitter converts parallel data into serial form and automatically adds start, parity, and stop bits. The data word length can be 5, 6, 7 or 8 bits. Parity may be odd or even. Parity checking and generation can be inhibited. The stop bits may be one, two or one and one-half when transmitting 5 bit code.

The HD-6402 can be used in a wide range of applications including modems, printers, peripherals and remote data acquisition systems. CMOS/LSI technology permits operating clock frequencies up to 2.0MHz (125K Baud) an improvement of 10 to 1 over previous PMOS UART designs. Power requirements, by comparison, are reduced from 300mW to 5mW. Status logic increases flexibility and simplifies the user interface.

HD-6101

CMOS Parallel Interface Element

Features

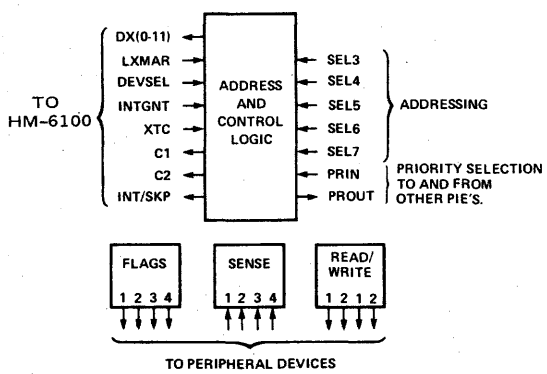
- HM-6100 COMPATIBLE
- LOW POWER – TYP. < 5.0μW STANDBY
- 4 – 11 VOLT SUPPLIES
- HIGH SPEED
- STATIC OPERATION

Description

The HD-6101 Parallel Interface Element (PIE) is a high speed, low power, silicon gate CMOS general purpose device which provides addressing, interrupt and control for a variety of peripheral functions, such as UARTs, FIFOs, Keyboards, etc. The PIE is designed to eliminate external logic. Data transfers between the HM-6100 CMOS Microprocessor and the HD-6101 are via IOT instructions, control lines and DX bus.

Data transfers between peripheral devices and the DX bus are controlled by the PIE via 2 read, 2 write, 4 sense and 4 flag functions. The A and B registers program write polarities, sense polarities, sense levels or edges, flag values and interrupt enables. The vector register has 10 bits writeable from the HM-6100 and 2 bits indicating the highest priority SENSE input that generated the interrupt.

Functions



- UNIVERSAL I/O PERIPHERAL CONTROLLER
- VECTORED PRIORITY INTERRUPT
- SET AND SENSE EXTERNAL FLAGS AND CONDITIONS VIA SOFTWARE

HD-4702/6405

Programmable Bit Rate Generator

FEATURES

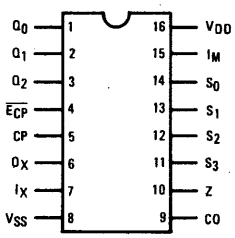
- HD-4702 – PROVIDES 13 COMMONLY USED BIT RATES
- HD-6405 – PROVIDES 15 COMMONLY USED BIT RATES
- USES A 2.4576MHz CRYSTAL/INPUT FOR STANDARD FREQUENCY OUTPUT (16 TIMES BIT RATE)
- TTL COMPATIBLE – OUTPUT WILL SINK 1.6mA
- LOW POWER DISSIPATION HD-6405 4.0mW TYP. @ 2.4576MHz HD-4702 4.5mW TYP. @ 2.4576MHz
- CONFORMS TO EIA RS-404
- ONE HD-4705 OR HD-6405 CONTROLS UP TO EIGHT TRANSMISSION CHANNELS
- INITIALIZATION CIRCUIT FACILITATES DIAGNOSTIC FAULT ISOLATION
- ON-CHIP INPUT PULL-UP CIRCUIT – HD-4702 ONLY

DESCRIPTION

The HD-4702/6405 Bit Rate Generator provides the necessary clock signals for digital data transmission systems, such as UART. It generates 13(HD-4702) or 15(HD-6405) commonly used bit rates using an on-chip crystal oscillator or an external input. For conventional operation generating 16 output clock pulses per bit period, the input clock frequency must be 2.4576MHz (i.e. 9600 Baud x 16 x 16, since there is an internal ÷16 prescaler). A lower input frequency will result in a proportionally lower output frequency.

The HD-4702/6405 can provide multi-channel operation with a minimum of external logic by having the clock frequency CO and the ÷ 8 prescaler outputs Q_0, Q_1, and Q_2 available externally. All signals have a 50% duty cycle except 1800 Baud and 2000 Baud which has less than 0.39% distortion and 3600 Baud which has less than 0.78% distortion.

The four rate select inputs (S_0-S_3) select which bit rate is at the output (Z). The table lists select code and output bit rate. Two of the 16 for the HD-4702 and one of the 16 for the HD-6405 do not select an internally generated frequency, but select an input into which the user can feed either a different frequency, or a static level (High or Low) to generate "ZERO BAUD".



The bit rate most commonly used in modern data terminals (110, 150, 300, 1200, 2400 Baud) require that no more than one input be grounded for the HD-4702, which is easily achieved with a single, 5-position switch.

The HD-4702/6405 has an initialization circuit which generates a common master reset for all flip-flops. This signal is derived from a digital differentiator that senses the first high level on the CP input after the $\overline{E_{CP}}$ input goes low. When $\overline{E_{CP}}$ is high, selecting the crystal input, CP must be low. A high level on CP would apply a continuous reset.

For the HD-4702, all inputs except I_X have on-chip pull-up circuits which provide TTL compatibility and eliminate the need to tie a permanently high input to V_{DD}.

PINOUT

CONNECTION DIAGRAM
DIP (TOP VIEW)

PIN NAMES

CP	External Clock Input
$\overline{E_{CP}}$	External Clock Enable Input (Active LOW)
I_X	Crystal Input
I_M	Multiplexed Input
S_0-S_3	Rate Select Inputs
CO	Clock Output
O_X	Crystal Drive Output
Q_0-Q_2	Scan Counter Outputs
Z	Bit Rate Output

NOTE:
The Flatpack version has the same pinouts (Connection Diagram) as the Dual-In-Line Package.

TRUTH TABLES

TABLE 1
CLOCK MODES AND INITIALIZATION

I_X	E_{CP}	CP	OPERATION
∿∿	H	L	Clocked from I_X
X	L	∿∿	Clocked from CP
X	H	H	Continuous Reset
X	L	⎍	Reset During First CP = HIGH Time

H = HIGH Level
L = LOW Level
X = Don't care
⎍ = 1st HIGH Level Clock Pulse after E_{CP} goes LOW
∿∿ = Clock Pulse

NOTE: Actual output frequency is 16 times the indicated Output Rate, assuming a clock frequency of 2.4576MHz.

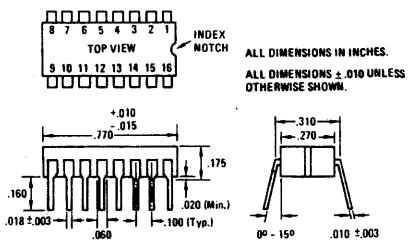


TABLE 2
TRUTH TABLE FOR RATE SELECT INPUTS

S_3	S_2	S_1	S_0	OUTPUT RATE (Z) HD-4702	OUTPUT RATE (Z) HD-6405

	$t_{WCP(H)}$	160			160			ns	

1. Input Current and Quiescent Power Supply Current are relatively higher for this device because of active pull-up circuits on all inputs except I_X. This is done for TTL compatibility.
2. Propagation Delays (t_{PLH} and t_{PHL}) and Output Transistion Times (t_{TLH} and t_{THL}) will change with Ouput Load Capacitance (C_L). Set-Up Times (t_s), Hold Times (t_h), and Minimum Pulse Widths (t_w) do not vary with load capacitance.
3. The first High Level Clock Pulse after $\overline{E_{CP}}$ goes Low must be at least 350ns long to guarantee reset of all Counters.
4. It is recommended that input rise and fall times to the Clock Inputs (CP, I_X) be less than 15ns.
5. For multichannel operation, Propagation Delay (CO to ON) plus Set-Up Time, Select to CO, is guaranteed to be ≤ 307ns.

PARAMETERS	SYMBOL	HD-4702A/6405A-2 MIN	TYP	MAX	HD-4702A/6405A-9 MIN	TYP	MAX	UNITS	TEST CONDITIONS
Propagation Delay, I_X to CO	t_{PLH} t_{PHL}			150 125			150 125	ns ns	$C_L \leq 7pF$ on OX
Propagation Delay, CP to CO	t_{PLH} t_{PHL}			110 100			110 100	ns ns	C_L = 15pF Input Transition Times ≤ 20ns
Propagation Delay, CO to O_n	t_{PLH} t_{PHL}			(5)			(5)	ns ns	
Propagation Delay, CO to Z	t_{PLH} t_{PHL}			40 35			40 35	ns ns	
Output Transition Time (except OX)	t_{TLH} t_{THL}			40 20			40 20	ns ns	
Propagation Delay, I_X to CO	t_{PLH} t_{PHL}			175 140			175 140	ns ns	$C_L \leq 7pF$ on OX
Propagation Delay, CP to CO	t_{PLH} t_{PHL}			130 110			130 110	ns ns	C_L = 50pF Input Transition Times ≤ 20ns
Propagation Delay, CO to O_n	t_{PLH} t_{PHL}			(5)			(5)	ns ns	
Propagation Delay, CO to Z	t_{PLH} t_{PHL}			45 40			45 40	ns ns	
Output Transition Time (except OX)	t_{TLH} t_{THL}			80 40			80 40	ns ns	
Set-Up Time, Select to CO	t_s	175			175			ns	$C_L \leq pF$ on OX
Hold Time, Select to CO	t_h	0			0			ns	
Set-Up Time, I_M to CO	t_s	175			175			ns	C_L = 15pF Input Transition Times ≤ 20ns
Hold Time, I_M to CO	t_h	20			20			ns	
Minimum Clock Pulse Width Low and High	$t_{w}CP(L)$ $t_{w}CP(H)$	60 0			60 0			ns ns	
Minimum I_X Pulse Width, Low and High	$t_{w}CP(L)$ $t_{w}CP(H)$	80 80			80 80			ns ns	

1. Input Current and Quiescent Power Supply Current are relatively higher for this device because of active pull-up circuits on all inputs except I_X. This is done for TTL compatibility.
2. Propagation Delays (t_{PLH} and t_{PHL}) and Output Transition Times (t_{TLH} and t_{THL}) will change with Ouput Load Capacitance (C_L). Set-Up Times (t_s), Hold Times (t_h), and Minimum Pulse Widths (t_w) do not vary with load capacitance.
3. The first High Level Clock Pulse after $\overline{ECP}$ goes Low must be at least 350ns long to guarantee reset of all Counters.
4. It is recommended that input rise and fall times to the Clock Inputs (CP, I_X) be less than 15ns.
5. For mulitchannel operation, Propagation Delay (CO to ON) plus Set-Up Time, Select to CO, is guaranteed to be ≤ 150ns.

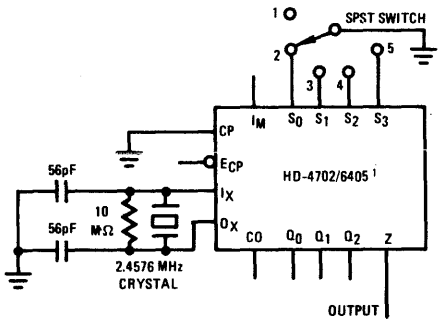
SINGLE CHANNEL BIT RATE GENERATOR

Figure 1 shows the simplest application of the HD-4702/6405. This circuit generates one of five possible bit rates as determined by the setting of a single pole, 5-position switch. The Bit Rate Output (Z) drives one standard TTL load or four low power Schottky loads over the full temperature range. The possible output frequencies correspond to 110, 150, 300, 1200, and 2400 or 3600 Baud. For many low cost terminals these five bit rates are adequate.



SIMULTANEOUS GENERATION OF SEVERAL BIT RATES

Fixed Programmed Multichannel Operation

Figure 2 shows a simple scheme that generates eight bit rates on eight output lines, using one HD-4702/6405 and one 93L34 Bit Addressable Latch. This and the following applications take advantage of the built-in scan counter (prescaler) outputs. As shown in the block diagram, these outputs (Q_0 to Q_2) go through a complete sequence of eight states for every half-period of the highest output frequency (9600 Baud). Feeding these Scan Counter Outputs back to the Select Inputs of the mulitplexer causes the HD-4702/6405 to interrogate sequentially the state of eight different frequency signals. The 93L34 8-Bit Addressable Latch, addressed by the same Scan Counter Outputs, reconverts the multiplexed single Output (Z) of the HD-4702/6405 into eight parallel output frequency signals. In the simple scheme of Figure 2, input S_3 is left open (HIGH) and the following bit rates are generated:

Q_0: 110 Baud Q_1: 9600 Baud Q_2: 4800 Baud
Q_3: 1800 Baud Q_4: 1200 Baud Q_5: 2400 Baud
Q_6: 300 Baud Q_7: 150 Baud

Other bit rate combinations can be generated by changing the Scan Counter to Selector interconnection or by inserting logic gates into this path.

SWITCH POSITION	HD-4702 BIT RATE	HD-6405 BIT RATE
1	110 Baud	110 Baud
2	150 Baud	150 Baud
3	300 Baud	300 Baud
4	1200 Baud	1200 Baud
5	2400 Baud	3600 Baud

INTELLEC® MICROCOMPUTER DEVELOPMENT SYSTEMS

Intellec. The first microcomputer development system with in-circuit emulation dramatically shortens development time for your microcomputer-based products.

Intellec. With the hardware and software you need to implement systems using Intel's 8021, 8048, 8049, 8080, 8085, 3000 and *future series microcomputers.*

Intellec. With its own 8080 processor, diskette-based operating system, all the memory, high speed peripherals and development software you need to design and debug your own product.

Intellec. Providing significant development cost savings by integrating the hardware/software effort and eliminating many man-hours in engineering, programming and testing.

Intellec. Modular in configuration so you can tailor your system to your particular needs—and budget. Begin with a basic 16K system, then expand as needed.

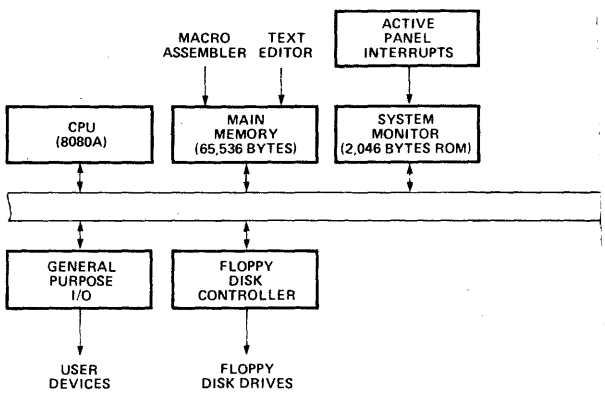
Intellec. With the in-house convenience you can't find with time-shared development systems. Enjoy the confidence that comes with Intel's top quality single-vendor service and support. All the development hardware, software, service, training and documentation you need is supplied in a single package.

Making your microprocessor design team more effective. To achieve optimum design of a microcomputer-based product at lowest cost, software and hardware must be considered simultaneously throughout the development cycle. The Intellec system provides the ICE™ concept to integrate the hardware/software efforts early in the cycle.

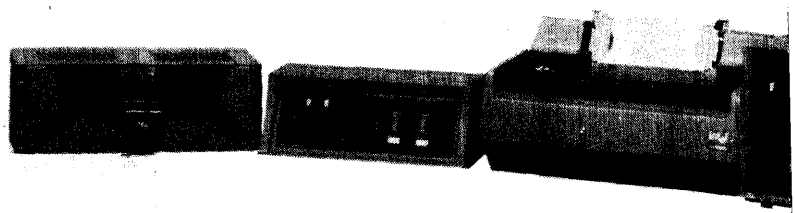
Software is tested on the actual prototype, not in a simulated environment designed to look like a description of the product.

Hardware and software development converge as soon as the microprocessor system bus is designed. At this early stage, memory and other Intellec resources can be shared to provide workable system configurations while the actual prototype boards are being built.

Both the Intellec text editor, and the resident PL/M-80 compiler or 8080/8085 or 8048 macro assemblers allow you to incorporate changes to prototype software in a quick, convenient manner, after a debug session.



Few companies in the past could enjoy the benefits of their own in-house computer-aided digital design center. The low cost of an Intellec system means that the smallest companies can now share in the benefits of design automation.



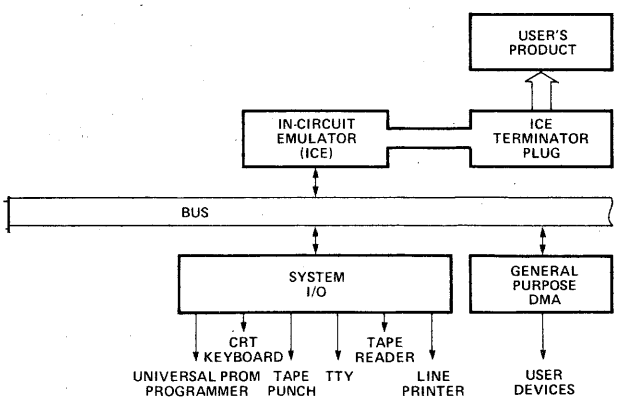
Modular configuration exactly fits your needs. The basic Intellec system includes an 8080-based central processing unit (with a 2 micro-second instruction cycle time, unlimited subroutine nesting, and 78 powerful instructions), 16K bytes of RAM memory, 2K bytes of ROM memory containing the system monitor, and hardware interfaces for a teletypewriter, CRT, line printer, high-speed paper tape reader and punch, and Universal PROM Programmer.

The Intellec system has an eight level nested priority interrupt structure and DMA memory modules; PROM memory can be expanded by the addition of two 6K or 16K PROM memory modules. You satisfy customized I/O requirements by adding general purpose I/O modules which contain four 8-bit input ports, four 8-bit output ports, and eight system interrupt lines. You maximize the efficiency of data transfers between Intellec memory and selected I/O devices by using direct memory access (DMA) modules. The Intellec universal bus supports multi-processor configurations and is not limited to any one Intel microcomputer family.

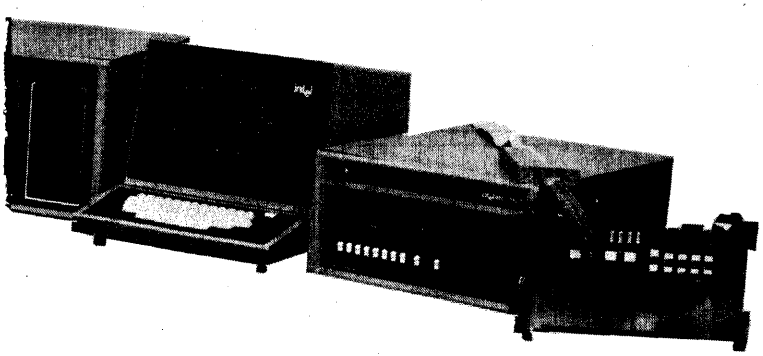
But the single feature providing you the greatest ease and versatility in developing your products—and the heart of the multi-processor system configuration—is the In-Circuit Emulator known as ICE.

In-circuit emulation provides a window into your prototype. The most significant and versatile feature of the Intellec system is the In-Circuit Emulator—ICE. ICE extends the Intellec systems powerful execution and debug capabilities into your own prototype and production systems. ICE plugs directly into your system replacing your prototype's CPU with a 40 pin plug which is component-level compatible with your microprocessor. ICE modules are available to support user configured 8048, 8085, 8080, 8021, 8049 and 3000 systems.

Intel, Intellec, ICE and Library Manager are trademarks of Intel Corporation.



©IC MASTER 1978



With ICE, you control, interrogate, revise and completely debug your system in its own environment. When you plug ICE into your system in place of your processor, you gain all the diagnostic power and flexibility built into the Intellec system.

You don't need to build your own special display or debug hardware to support your development as these are integral parts of the Intellec system. You can use Intellec memory and input/output facilities in the early phases of testing your prototype. Then, on a step-by-step basis, you replace shared system resources with prototype resident memory and I/O.

ICE checks for hardware and software break conditions. A special external breakpoint probe is provided to attach to any logic signal on a prototype board to detect hardware conditions not directly accessible to the microprocessor bus.

ICE provides the capability to examine and alter CPU registers, main memory, pin and flag values, and automatically collects and stores address, data and status information for machine cycles emulated. And, for the first time, you can examine and modify your system using symbolic references instead of absolute values.

Powerful diskette software reduces program development time. Intel's System Implementation Supervisor (ISIS) is a general purpose, high speed data handler and file manipulation system for use with the Intellec system and its peripherals. It significantly reduces program development time during edit, assembly, compilation, and debugging of programs.

ISIS provides high speed I/O and data storage for the Intellec system. ISIS has a 1/2 million byte storage capacity with two diskette drives, and can store up to 200 program files per diskette.

A wide range of system commands is supplied, offering powerful file and program manipulation features in an easy to use English context. Dynamic allocation of diskette sectors, variable length files and peripheral device independence are all standard features of ISIS. The ISIS text editor provides powerful string search, substitution, insertion, and deletion commands.

The ISIS-II diskette operating system also includes a macro assembler which generates relocatable code, a relocation and linkage package, and a Library Manager™.

The linkage capability enables the user to link several independently assembled or compiled relocatable object modules to form a single relocatable object module.

During the linking process, all external address and data references between program modules are satisfied automatically.

Programs are created, edited, assembled, executed and debugged without paper tape handling. Listings produced by the macro-assembler and PL/M-80 can be directed to diskette for later interrogation from the high speed Intellec console CRT/keyboard, or written directly to line printer.

Resident PL/M brings you high-level programming. The PL/M-80 compiler runs directly on the Intellec system using the ISIS software operating system.

To the user, this means faster development time, lower programming costs, better program reliability, more concise documentation and easier program maintenance.

The PL/M-80 compiler produces efficient relocatable code which can be easily linked with other PL/M-80 and/or assembly language programs.

The PL/M-80 code optimizer performs compile-time analysis, resulting in tighter, more efficient code generation.

Other features of the resident PL/M-80 compiler include: "Innerlist" of generated assembly language code: cross reference listing; listing format options for easy page formatting; easy linkage to external code and data; all required constructs for structured programming and capability for defining re-entrant procedures.

With PL/M-80 the user can create, compile, modify, link, relocate and debug programs entirely on the Intellec system itself with no requirements for large in-house computers or time-sharing services.

©IC MASTER 1978

SYMBOLIC DEBUGGING CAPABILITY

ICE-85 allows the user to make symbolic references to I/O ports, memory addresses and data in his program. Symbols and PL/M statement number may be substituted for numeric values in any of the ICE-85 commands. The user is relieved from looking up addresses of variables or program subroutines.

The user symbol table generated along with the object file during a PL/M-80 compilation or by the ISIS-II 8080/8085 Macro Assembler is loaded into the Intellec® System memory along with the user program which is to be emulated. The user may add to this symbol table any additional symbolic values for memory addresses, constants, or variables that are found useful during system debugging. By referring to symbol memory addresses, the user can examine, change or break at the intended location.

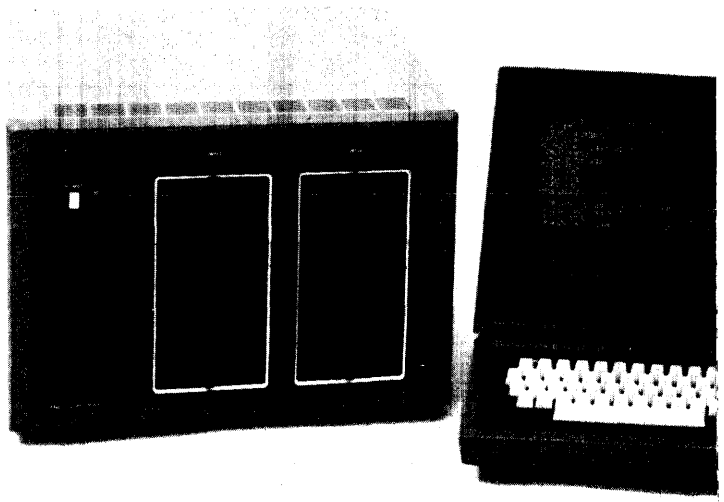
ICE-85 provides symbolic definition of all 8085 registers, interrupt bits and flags. The following symbolic references are also provided for user convenience: TIMER, the low-order 16 bits of a register containing the number of 2 MHz clock pulses elapsed during emulation; HTIMER, the high-order 16 bits of the timer counter; PPC, the address of the last instruction emulated; BUFFERSIZE, the number of frames of valid trace data (between 0 and 1022).

PERSONALITY GROUPED DISPLAYS

Trace data in the 1023 by 42-channel real-time trace memory buffer is displayed in easy to read format. The user has the option to specify trace data displays in actual 8085 assembler instruction mnemonics. The data collected from the External Trace Module can be grouped and symbolically named according to user specifications and displayed in the appropriate number base designation. Simple ICE-85 commands allow the user to select any portion of the 42K-bit trace buffer for immediate display.

MEMORY AND I/O MAPPING

Memory and I/O for the user system can be resident in the user system or "borrowed" from the Intellec® System through ICE-85's mapping capability.



ICE-85 separates user memory into 32 2K blocks. Each block of memory can be defined independently. The user may assign Intellec® System equivalents to take the place of devices not yet designed for the user system during prototyping. In addition, Intellec® System memory or I/O can be accessed in place of suspect user system devices during prototyping or production checkout.

The user can also designate a block of memory or I/O as nonexistent. ICE-85 issues error messages when memory or I/O designated as nonexistent is accessed by the user program.

INTEGRATED HARDWARE/SOFTWARE DEVELOPMENT

The user prototype need consist of no more than an 8085 CPU socket and a user bus to begin integration of software and hardware development efforts. Through ICE-85 mapping capabilities, Intellec® System equivalents can be accessed for missing prototype hardware. Hardware designs can be tested using the system software which will drive the final product.

The system integration phase, which can be so costly when attempting to mesh completed hardware and software products, becomes a convenient two-way debug tool when begun early in the design cycle.

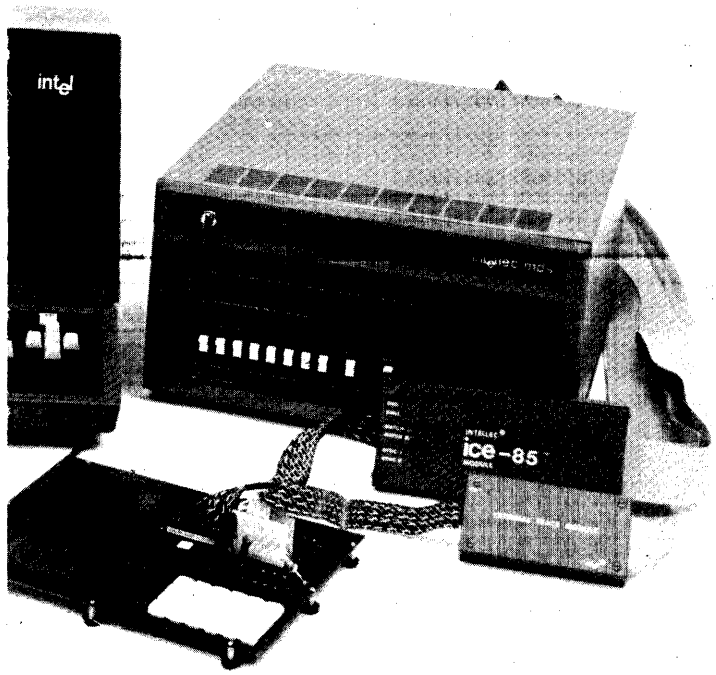
TYPICAL ICE INTERROGATION AND UTILITY COMMANDS

DISPLAY/ CHANGE	Display/Changes the values of symbols and the contents of 8085 registers, pseudo-registers, status flags, interrupt bits, I/O ports and memory.
EVALUATE	Displays the value of an expression in the binary, octal, decimal or hexadecimal.
SEARCH	Searches user memory between locations in a user program for specified contents.
CALL	*Emulates* a procedure starting at a specified memory address in user memory.
ICALL	*Executes* a user-supplied procedure starting at a specified memory address in the Intellec® System memory.
EXECUTE	Saves emulated program registers and emulates a user-supplied subroutine to access peripheral chips in the user's system.

©IC MASTER 1978

REAL TIME TRACE

ICE-85 captures valuable trace information from the emulating CPU and the External Trace Module while the user is executing programs in real time. The 8085 status, the user memory or port addressed, the data read or written, the serial data lines and data from 18 external signals, is stored for the last 1023 machine states executed (511 machine cycles). This provides ample data for determining how the user system was reacting prior to emulation break. It is available whether the break was user-initiated or the result of an error condition.



For detailed information on the actions of CPU registers, flags, or other system operations, the user may operate in single or multi-step sequences tailored to system debug needs.

EXTERNAL TRACE MODULE

TTL level signals from 18 points in the user system may be synchronously sampled by the External Trace Module and collected in ICE-85's trace buffer. The signals can be collected from a single peripheral chip via the supplied 40-pin DIP clip or may be placed by the user on up to 18 separate signal nodes using the supplied 18 individual probe clips. These signals are included in the 42-channel breakpoint comparisons and clock qualifiers. Also, data from these 18 channels may be displayed in each to read, user-defined groupings.

SYNCHRONOUS OPERATION WITH OTHER DESIGN AIDS

ICE-85 can be synchronized with other Intellec® design aids by means of two external synchronization lines. These lines are used to enable and disable ICE-85 trace data collection and to cause break conditions based on an external signal which may not be included in the ICE-85 breakpoint registers. In addition, ICE-85 can generate signals on these lines which may be used to control other design aids.

BREAK REGISTERS/TRACE MEMORY

ICE-85 has two breakpoint registers which are used to break emulation, and two trace qualifier registers which are used to control the collection of trace data during emulation. Each register is 42 entries wide, one entry for each channel and each entry can take any one of the three values 0, 1 or "don't care".

The trace buffer, also 42 entries wide, collects data sampled from 24 8085 processor channels and 18 external channels sampled by the External Trace Module. The signals collected from the 8085 include address lines, data lines, status lines and serial input and output lines. The 18 channels extending from the External Trace Module synchronously sample and collect into the trace buffer any user-specified TTL compatible signal from the rest of the prototype system. "Break" and "trace qualification" may therefore occur as a result of a match of any combination of up to 42 channels of CPU and external circuitry signals.

EMULATION CONTROLS AND COMMANDS

GROUP	Defines into a symbolically named group, a channel or combination of channels from the 8085 Microcprocessor and/or the External Trace Module.
GO	Initiates real-time emulation and controls emulation break conditions.
STEP	Initiates emulation in single instruction steps. User may specify the type and amount of information displayed following each step, and define conditions under which stepping should continue.
PRINT	Prints the user-specified portion of the trace memory to the selected list device.

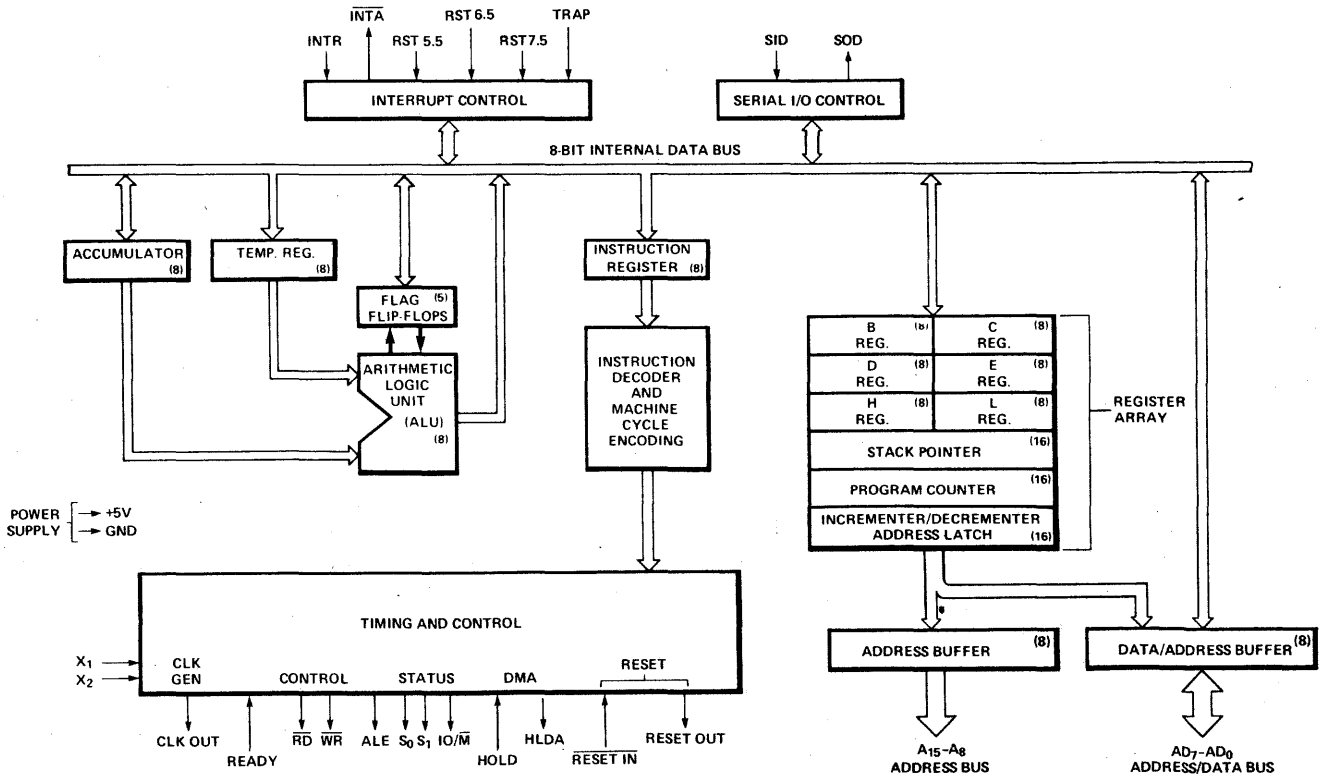
PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

8085A
SINGLE CHIP 8-BIT N-CHANNEL MICROPROCESSOR



- **Single +5V Power Supply**
- **100% Software Compatible with 8080A**
- **1.3 μs Instruction Cycle**
- **On-Chip Clock Generator (with External Crystal or RC Network)**
- **On-Chip System Controller**
- **Four Vectored Interrupts (One is non-Maskable)**
- **Serial In/Serial Out Port**
- **Decimal, Binary and Double Precision Arithmetic**
- **Direct Addressing Capability to 64K Bytes of Memory**

The Intel® 8085A is a new generation, complete 8 bit parallel central processing unit (CPU). Its instruction set is 100% software compatible with the 8080A microprocessor, and it is designed to improve the present 8080's performance by higher system speed. Its high level of system integration allows a minimum system of three IC's: 8085A (CPU), 8156 (RAM) and 8355/8755 (ROM/PROM).

The 8085A incorporates all of the features that the 8224 (clock generator) and 8228 (system controller) provided for the 8080, thereby offering a high level of system integration.

The 8085A uses a multiplexed Data Bus. The address is split between the 8 bit address bus and the 8 bit data bus. The on-chip address latches of 8155/8355/8755 memory products allows a direct interface with 8085A.

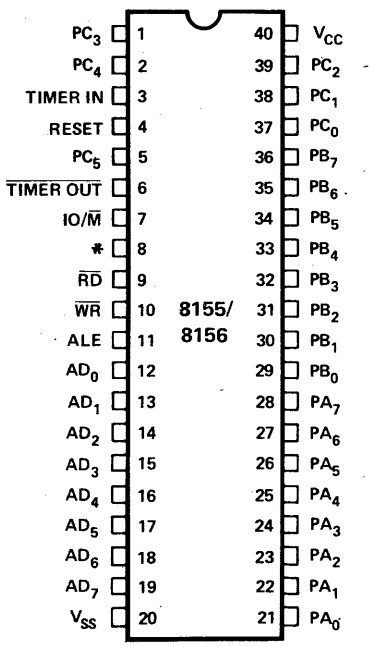
8155/8156

2048 BIT STATIC MOS RAM WITH I/O PORTS AND TIMER

PRELIMINARY
Notice: This is not a final specification. Some parametric limits are subject to change.

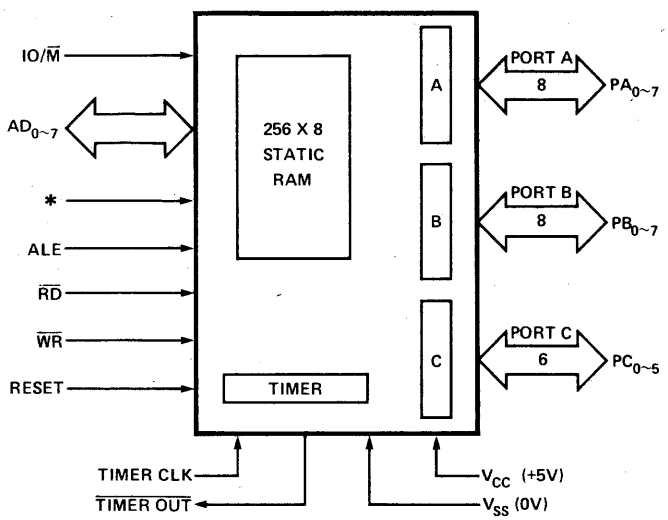
8155 — Active Low Chip Enable ($\overline{CE}$)
8156 — Active High Chip Enable (CE)

*Directly Compatible With 8085 CPU



- 256 Word x 8 Bits
- Single +5V Power Supply
- Completely Static Operation
- Internal Address Latch
- 2 Programmable 8 Bit I/O Ports
- 1 Programmable 6 Bit I/O Port
- Programmable 14 Bit Binary Counter/Timer
- Multiplexed Address and Data Bus
- 40 Pin DIP

The 8155 and 8156 are RAM and I/O chips to be used in the MCS-85™ microcomputer system. The RAM portion is designed with 2K bit static cells organized as 256 x 8. They have a maximum access time of 400ns to permit use with no wait states in 8085 CPU.



The I/O portion consists of three general purpose I/O ports. One of the three ports can be programmed to be status pins, thus allowing the other two ports to operate in handshake mode.

A 14 bit programmable counter/timer is also included on chip to provide either a square wave or terminal count pulse for the CPU system. It operates in binary countdown mode, and its timer modes are programmable.

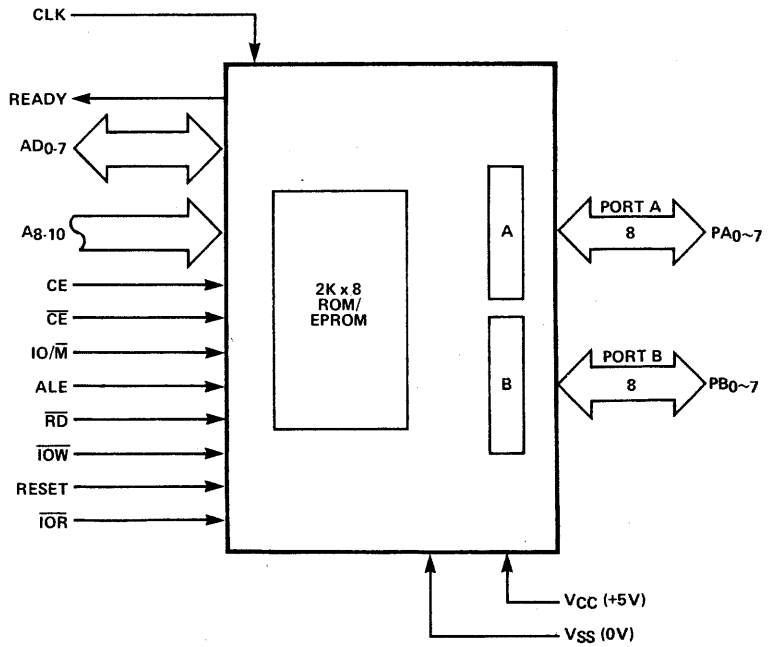
8355-16,384 BIT ROM WITH I/O
8755A-16,384 BIT EPROM WITH I/O
*Directly Compatible With 8085 CPU

- 2048 Words × 8 Bits
- Single +5V Power Supply
- Internal Address Latch
- 2 General Purpose 8 Bit I/O Ports
- Each I/O Port Line Individually Programmable as Input or Output
- Multiplexed Address and Data Bus
- 40 Pin DIP



The 8355 is a ROM and I/O chip to be used in the MCS-85™ microcomputer system. The 8755 is a UV erasable and electrically reprogrammable ROM (EPROM) and I/O chip. The ROM portion is organized as 2048 x 8. It has maximum access time of 400 ns to permit use with no wait states in 8085 CPU.

The I/O portion consists of two general purpose I/O ports. Each I/O port has 8 port lines, and each I/O port line is individually programmable as input or output.

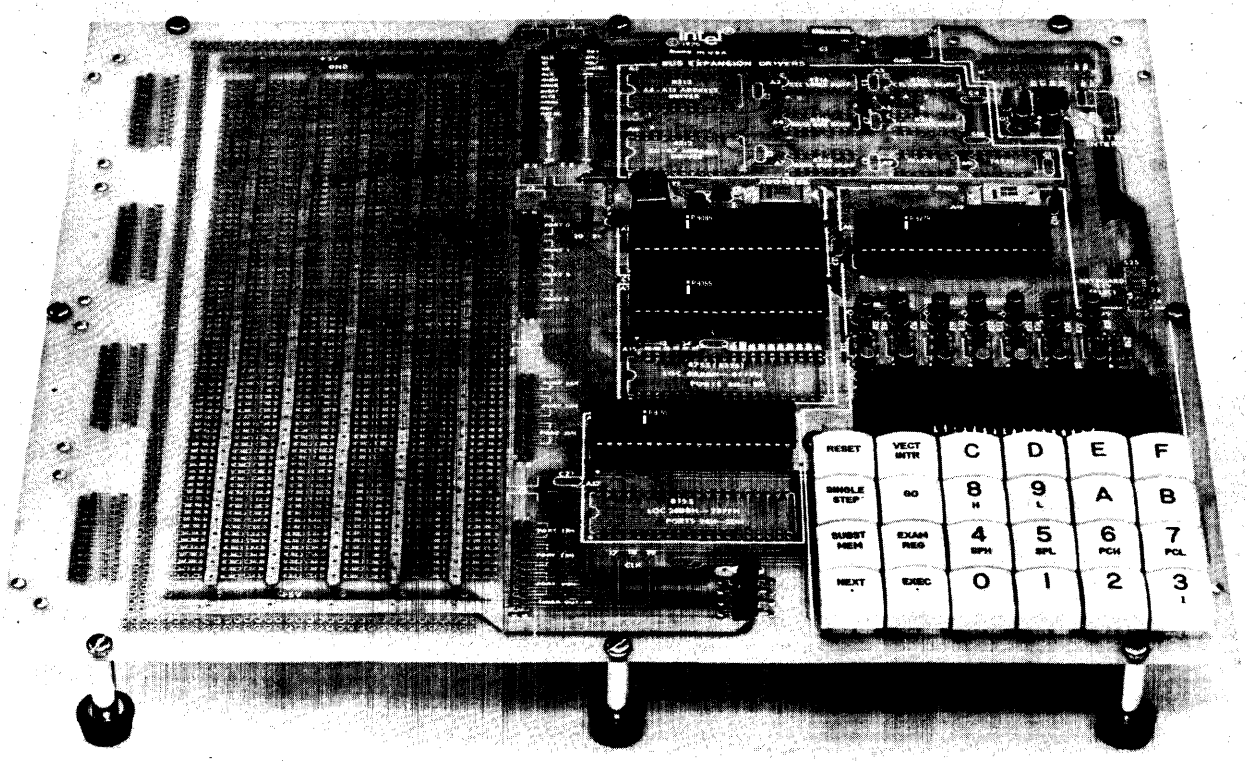
SDK-85
MCS-85™ SYSTEM DESIGN KIT



PRELIMINARY
Notice: This is not a final specification. Some parameter limits are subject to change.

- Complete Single Board Microcomputer System Including CPU, Memory and I/O
- Easy to Assemble Kit-Form
- High-Performance 3MHz 8085 CPU (1.3 μs Instruction Cycle)
- Popular 8080A Instruction Set
- Interfaces Directly With TTY
- Interactive LED Display and Keyboard.
- Large Wire-Wrap area for Custom Interfaces
- Extensive System Monitor Software in ROM
- Comprehensive Design Library Included
- Low Cost

The MCS-85 System Design Kit (SDK-85) is a complete, single board, microcomputer system in kit form. It contains all necessary components, including LED Display, Keyboard, resistors, caps, crystal and miscellaneous hardware to complete construction. Included is a preprogrammed ROM that contains the system monitor for general software utilities and system diagnostics.

The SDK-85 includes 6 digit LED display and 24 key-keyboard for a direct insertion, examination and execution of a user's program. In addition, it can be directly interfaced with a teletype terminal.

The SDK-85 is an inexpensive, high-performance prototype system that has designed-in flexibility for simple interface to the user's application.

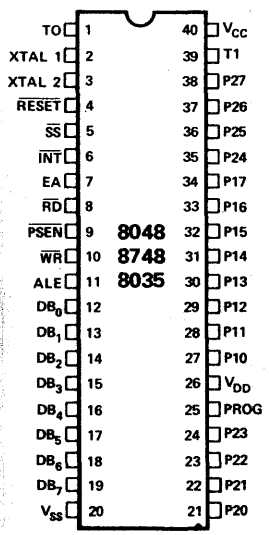
8048/8748/8035

SINGLE COMPONENT 8-BIT MICROCOMPUTER

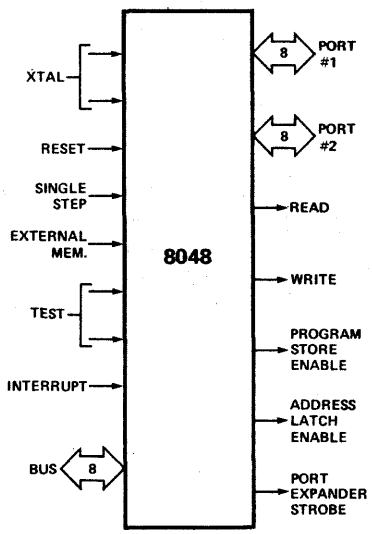
***8048 Mask Programmable ROM**
***8748 User Programmable/Erasable EPROM**
***8035 External ROM or EPROM**

- **8-Bit CPU, ROM, RAM, I/O in Single Package**
- **Interchangeable ROM and EPROM Versions**
- **Single 5V Supply**
- **2.5 µsec and 5.0 µsec Cycle Versions All Instructions 1 or 2 Cycles.**
- **Over 90 Instructions: 70% Single Byte**
- **1K x 8 ROM/EPROM 64 x 8 RAM 27 I/O Lines**
- **Interval Timer/Event Counter**
- **Easily Expandable Memory and I/O**
- **Compatible with MCS-80™ Peripherals**
- **Single Level Interrupt**



The Intel® 8048/8748/8035 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process.

The 8048 contains a 1K x 8 program memory, a 64 x 8 RAM data memory, 27 I/O lines, and an 8-bit timer/counter in addition to on board oscillator and clock circuits. For systems that require extra capability, the 8048 can be expanded using standard memories and MCS-80™ (8080A) peripherals. The 8035 is the equivalent of an 8048 without program memory.



To reduce development problems to a minimum and provide maximum flexibility, three interchangeable pin-compatible versions of this single component microcomputer exist: the 8748 with user-programmable and erasable EPROM program memory for prototype and preproduction systems, the 8048 with factory-programmed mask ROM program memory for low-cost high volume production, and the 8035 without program memory for use with external program memories.

This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8048 has extensive bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over two bytes in length.

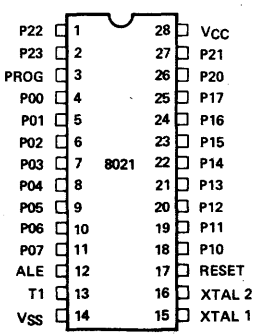
8021

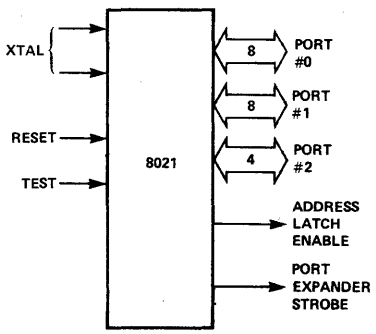
SINGLE COMPONENT 8-BIT MICROCOMPUTER

- **8-Bit CPU, ROM, RAM, I/O in Single 28-Pin Package**
- **Single 5V Supply (+4.5V to 6.5V)**
- **10 μsec Cycle; All Instructions 1 or 2 Cycles**
- **Instructions —8748 Subset**
- **High Current Drive Capability—2 Pins**
- **1K × 8 ROM**
  64 × 8 RAM
  21 I/O Lines
- **Interval Timer/Event Counter**
- **Clock Generated With Single Resistor or Inductor**
- **Zero-Cross Detection Capability**
- **Easily Expandable I/O**



The Intel® 8021 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process. The features of the 8021 include a subset of the 8048 optimized for low-cost, high volume applications, plus additional I/O flexibility and power.

The 8021 contains a 1K X 8 program memory, a 64 X 8 data memory, 21 I/O lines, and an 8-bit timer/event counter, in addition to on-board oscillator and clock circuits. For systems that require extra I/O capability, the 8021 can be expanded using the 8243 or discrete logic.



This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8021 has bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over two bytes in length.

To minimize development problems and maximize flexibility, an 8021 system can be easily designed using the 8021 emulation board, EMB-21. The EMB-21 contains a 40-pin socket which can accomodate either the 8748 shipped with the board or an ICE-48 plug. Also, the necessary discrete logic to reproduce the 8021's additional I/O features is included.

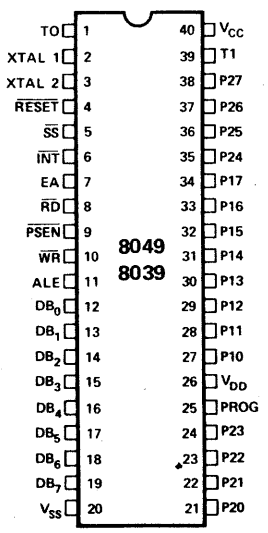
8049/8039
SINGLE COMPONENT 8-BIT MICROCOMPUTER

EARLY PRODUCTION

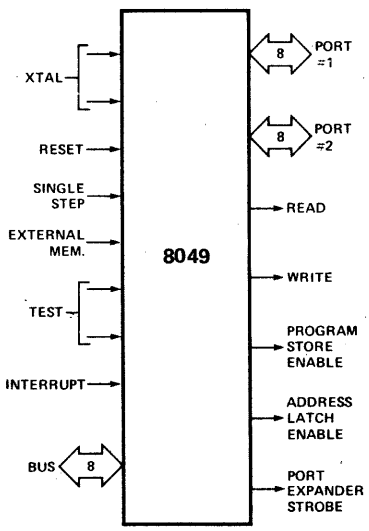
*8049 Mask Programmable ROM
*8039 External ROM or EPROM

- 8-Bit CPU, ROM, RAM, I/O in Single Package
- Single 5V ±10% Supply
- 2.5 μsec Cycle; All Instructions 1 or 2 Cycles
- Over 90 Instructions: 70% Single Byte
- Pin Compatible with 8048/8748
- 2K x 8 ROM
  128 x 8 RAM
  27 I/O Lines
- Interval Timer/Event Counter
- Easily Expandable Memory and I/O
- Compatible with MCS-80/85™ Peripherals
- Single Level Interrupt



The Intel® 8049/8039 is a totally self-sufficient 8-bit parallel computer fabricated on a single silicon chip using Intel's N-channel silicon gate MOS process.

The 8049 contains a 2K x 8 program memory, a 128 x 8 RAM data memory, 27 I/O lines, and an 8-bit timer/counter in addition to on board oscillator and clock circuits. For systems that require extra capability, the 8049 can be expanded using standard memories and MCS-80™/MCS-85™ peripherals. The 8039 is the equivalent to an 8049 without program memory.



To reduce development problems to a minimum and provide maximum flexibility, two interchangeable pin-compatible versions of this single component microcomputer exist: the 8049 with factory-programmed mask ROM program memory for low-cost high volume production, and the 8039 without program memory for use with external program memories in prototype and preproduction systems.

This microprocessor is designed to be an efficient controller as well as an arithmetic processor. The 8049 has extensive bit handling capability as well as facilities for both binary and BCD arithmetic. Efficient use of program memory results from an instruction set consisting mostly of single byte instructions and no instructions over two bytes in length.

8041/8741 UNIVERSAL PERIPHERAL INTERFACE

- Fully Compatible with MCS-80™ and MCS-48™ Microprocessor Families
- Single Level Interrupt
- 8-Bit CPU Plus ROM, RAM, I/O, Timer, and Clock in a Single Package
- Single 5V Supply
- Alternative to Custom LSI
- Pin Compatible ROM and EPROM Versions
- 1Kx8 ROM/EPROM, 64x8 RAM, 18 Programmable I/O Pins
- Asynchronous Data Register for Interface to Master Processor
- Expandable I/O

8243 INPUT/OUTPUT EXPANDER

- Low Cost
- Simple Interface to MCS-48™ Microcomputers
- Four 4-Bit I/O Ports
- AND and OR Directly to Ports
- 24-Pin DIP
- Single 5V Supply
- High Output Drive
- Direct Extension of Resident 8048 I/O Ports

8271 PROGRAMMABLE FLOPPY DISK CONTROLLER

- Supports Standard or Minifloppy Drives
- IBM3740 Soft Sectored Format Compatible
- Associative Scan Search Commands
- Programmable Record Lengths
- Multi-Sector Capability
- Maintain Dual Drives with Minimum Software Overhead Expandable to 4 Drives
- Automatic Read/Write Head Positioning and Verification
- Internal CRC Generation and Checking
- Programmable Step Rate, Settle-Time, Head Load Time, Head Unload Index Count
- Fully Compatible with 8080/8085 CPU
- Single +5 Volt Supply
- 40-Pin Package

8273 SDLC PROTOCOL CONTROLLER

- IBM SDLC Compatible
- Frame Level Commands
- Full Duplex, Half Duplex, or Loop SDLC Operation
- Two User Progrrammable Modem Control Ports
- Up to 64K Baud Transfers
- Automatic FCS (CRC) Generation and Checking
- Programmable NRZI Encode/Decode
- N-Bit Reception Capability
- Minimum CPU Overhead
- Digital Phase Locked Loop Clock Recovery
- Fully Compatible with 8080/8085 CPU
- Single +5 Volt Supply
- 40-Pin Package

8275 PROGRAMMABLE CRT CONTROLLER

- Programmable Screen and Character Formats
- Six Independent Visual Field Attributes
- Eleven Visual Character Attributes (Graphic Capability)
- Cursor Control (4 Types)
- Light Pen Detection and Registers
- Fully MCS-80™ and MCS-85™ Compatible
- Dual Row Buffers
- Programmable DMA Burst Mode
- Single +5 Volt Supply
- 40-Pin Package

8279, 8279-5 PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

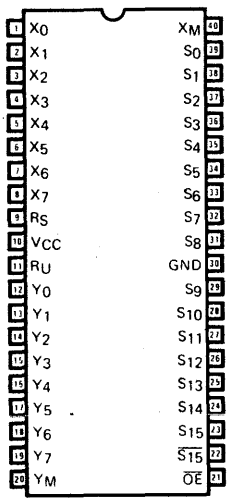
- MCS-85™ Compatible 8279-5
- Simultaneous Keyboard Display Operations
- Scanned Keyboard Mode
- Scanned Sensor Mode
- Strobed Input Entry Mode
- 8 Character Keyboard FIFO
- 2-Key Lockout or N-Key Rollover
- Dual 8 or 16 Numerical Display
- Single 16-Character Display
- Right or Left Entry 16-Byte Display RAM
- Mode Programmable from CPU
- Programmable Scan Timing
- Interrupt Output on Key Entry

©IC MASTER 1978

8×8 Multiplier

57558/67558

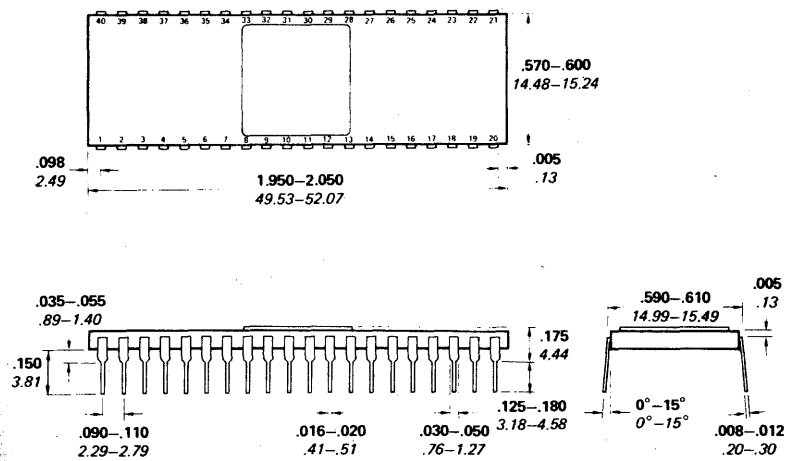
FEATURES



- Unsigned, Signed or Mixed Multiplication
- Rounding Inputs for Signed or Unsigned Operation
- Inverted Most Significant Output For Signed Expansion
- Three-State Outputs for Bus Operation
- High Speed – 100 ns Typ

PART NUMBER	PACKAGE	TEMPERATURE RANGE
67558	D40	0°C TO +75°C
57558	D40	-55°C TO +125°C

DESCRIPTION



The 57558/67558 is a high speed 8 x 8 combinatorial Multiplier which can multiply two eight-bit unsigned or signed 2s complement numbers and generate the sixteen-bit unsigned or signed product. Each input operand X and Y has an associated Mode control line, X_M and Y_M respectively. When a Mode control line is at a Low logic level the operand is treated as an unsigned eight-bit number while if the Mode control is at a High logic level the operand is treated as an eight-bit signed 2s complement number. Two additional inputs R_S and R_U allow the addition of a bit in the multiplier array at the appropriate bit positions for rounding signed or unsigned fractional numbers. The most significant product bit is available in both True and Complement form to assist in expansion to larger signed multipliers. The product outputs are three-state, controlled by an active Low Output Enable which allows several Multipliers to be connected to a parallel bus or to be used in a pipelined system. The device uses a single +5V power supply and is packaged in a standard 40-pin DIP.

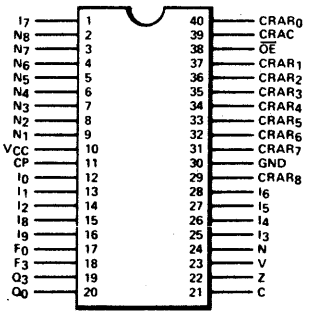
Microprogram Controller

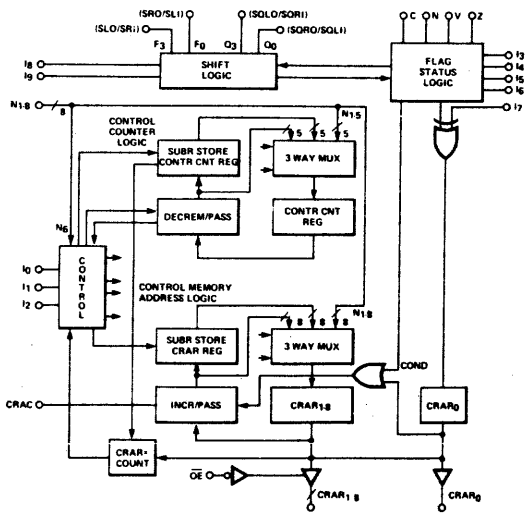
57110/67110



FEATURES

- Addresses 512 words
- Easily expandable
- Microsubroutine capability
- Loop control
- Multi-path branching
- Shift control for data slice
- Three-state output bus
- High speed
- Standard 40-pin package

APPLICATIONS



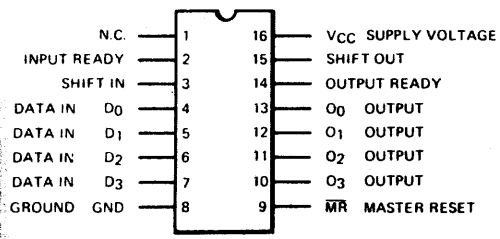
- Minicomputer microprogram controller
- High-speed disk controller
- Line printer controller
- CRT terminal controller

PIN CONFIGURATION

The 57110/67110 Microprogram Controller (MPC) is a member of the 57000/67000 computer logic family of high-performance bipolar compatible Schottky TTL components. The device is designed to work in conjunction with 4-bit slice microprocessors and standard ROMs and PROMs for the design of extremely powerful computing systems. The power and flexibility of the MPC also allow it to be used for general purpose control applications.

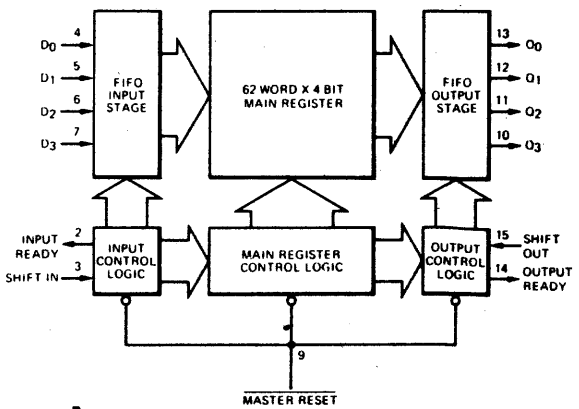
BLOCK DIAGRAM

FIFO



57401/67401

The 57401/67401 First-In, First-Out (FIFO) Serial Memory is used to receive data at one clock rate and to transmit this data at a different clock rate. The device is useful whenever data is incoming to a system asynchronously to the rate at which the system is operating such as in data acquisition. The 57401/67401 is arranged in 64 word by 4-bit wide architecture and is provided with separate input/output clocks and input/output ready indicator lines. Common active low and master reset are provided. Five volt power supplies are used with TTL input/output levels at data rates in excess of 10MHz. Military and commercial temperature range devices are available.



PRODUCT FEATURES

- 10MHz shift in/shift out rates
- Advanced Schottky bipolar processing
- TTL inputs and outputs
- Readily expandable in word and bit dimensions
- Asynchronous or synchronous operation
- Pin compatible with Fairchild's F3341 MOS FIFO and ten times as fast.

National's Full Spectrum of Microprocessors

National Semiconductor, offers the broadest line of microprocessors of any semiconductor manufacturer in the world. National has expanded its microprocessor base so any microprocessor application can be designed and produced using its products. From the simplest electronic toy or control mechanism to large control arrays, point-of-sale systems, and large data-processing systems, National can supply your needs. Some of the features and benefits of dealing with National follow.

- Cost effectiveness – because of our variety, our microprocessors afford designs that can be tailored to a multitude of applications
- Broad product family of microprocessors and peripherals:
- 16-Bit COMPUTATION microprocessors for precision control functions
- 8-Bit BYTE HANDLING microprocessors for terminals
- 4/8-Bit LOW-COST CONTROL microprocessors for industrial controllers
- Second sourced families
- Ready availability – off-the-shelf shopping
- Micro-Plus – special reliability and quality program
- Full development system support – all the way from the high-powered PACE development system (with numerous software packages and a DOS) to low-cost development systems (for PACE and SC/MP) to do-it-yourself PACE and SC/MP kits

National Semiconductor also offers the most extensive line of CPU-to-peripheral support products – for digital input/output, communications, peripheral control, and memory. And National Semiconductor is expanding the support lines, so you can expect to see even more!

Microprocessors and Peripherals from National – Compatibility Plus

©IC MASTER 1978

For a Full Spectrum of Applications

National's INS2650 Family

The 2650 Family consists of a series of memory and peripheral components built around the 2650A 8-bit microprocessor. This second-sourced processor family offers excellent byte and bit manipulation for a variety of applications.

Seventy-five variable-length instructions – one, two, and three bytes – comprise the instruction set, thus minimizing memory requirements. Some of National's INS2650 family features:

- Single-phase clock, using only one interface pin and requiring only a normal TTL voltage swing, no special clock driver is required
- Single 5-volt power supply
- TRI-STATE data and address signals, simplifying system design and allowing asynchronous memory and I/O interface signals – means DMA is easy to implement
- Single-level, address-vectoring interrupt mechanism – means that the interrupting device can force execution of code at a device-determined memory location

National's INS8080A Family

Positioned between the cost-effective SC/MP and the highly versatile PACE, National's INS8080A can be used in systems which range from a few family components to designs which utilize its full capabilities. National offers the broadest line of peripheral circuits and memories to complement the basic 8080A CPU, with most parts available *now*. National's 8080A features and benefits:

- Family approach to system design
- Complete CPU group
- Programmable input/output concepts
- Multiple source availability
- Complete line of support components
- Total product support

National's N8080 family is supported by industry-standard design kits, easy-to-use development systems, and a full complement of cross and resident assemblers. Various components and software also are available to support the N8080 family from experimentation to final production.

National's SC/MP Family

SC/MP is National's simplest true microprocessor. It is the lowest-cost replacement for electrical, mechanical and hydraulic control systems. Typical applications include business machines, scales, cash registers and other human-interface devices.

The growing family of SC/MP devices presently includes PMOS and a new, double-speed NMOS CPU (SC/MP-II), a RAM-I/O chip with 16 I/O lines, and a variety of bus-oriented interface and memory devices. The SC/MP CPU itself incorporates unique multiprocessor control logic to facilitate distributed processing systems with the lowest number of components. SC/MP also has a built-in Clock, Parallel and Serial I/O; it uses low power; and it can interface to standard memory and peripheral products. Also available is a BASIC high-level language called NIBL, which can be obtained in ROM form for fast software development.

SC/MP CPU, RAM, and ROM/PROM application cards are also available to help speed prototyping and production for users who need these functions ready-made. To develop programs, use the SC/MP Low Cost Development System – or the PACE Development System, which has a full complement of support software for preparing SC/MP programs.

National's FIPS Family

FIPS (INS4004) is National's second source to the MCS-4* family. This was the first production microprocessor system, and it is still a popular 4-bit microprocessor because of its simplicity and low cost. The INS4004 is fabricated using P-channel silicon gate MOS technology.

Some of National's INS4004 features:

- Four-bit parallel CPU
- Applicable for use in test systems, terminals, billing machines, process control, and random logic replacement
- Readily interfaces with keyboards, switches, displays, A/D converters, and various peripheral equipment
- Ability of CPU to address 4K 8-bit instruction words, 5120 bits of RAM, up to 16 4-bit input ports, and 16 4-bit output ports
- In volume production

*A registered trademark of Intel Corporation

National's COPS Family

Calculator Oriented Processor Systems (COPS) provide a low-cost solution to low-end computing and control problems. Manufactured by National's volume-proven P-channel MOS/LSI calculator process, COPS offers an attractive, low-risk alternative to custom LSI.

The COPS Family includes three different CPU/memory controller chips, as well as a variety of special-purpose drivers and interfaces to handle displays, keyboards, printers, and other peripherals.

National's IDM 2900 Family

The IDM 2900 Bipolar Slice Family from National consists of a series of devices using low-power Schottky TTL technology. The heart of the IDM 2900 family is the IDM 2901A 4-Bit Slice CPU, which has become the industry standard in slice architecture. An outstanding feature of the IDM 2900 family is that they may be used in sundry combinations to emulate a multitude of CPU architectures – in contrast to fixed-instruction microprocessors, which can execute only one set of instructions. Also, the word length of an IDM 2900-based microprocessor may be any multiple of 4 bits. Each IDM 2900 device performs a basic function, which is controlled by an appropriate microinstruction of a microprogrammed system.

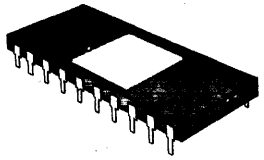
The fast bipolar speed, the design flexibility, and the 4-bit-slice feature of the IDM 2900 Family add to the already broad base of microprocessors and support devices available from National Semiconductor.

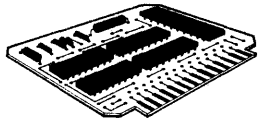
National's PACE Family

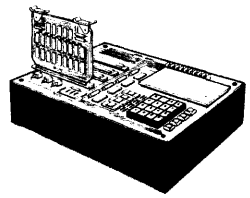
PACE is a complete, 16-bit "minicomputer on a chip." Its wide word length, hardware-vectored interrupt structure, and sophisticated addressing modes make it ideal for laboratory instrumentation, data acquisition and process control applications, where number handling and fast response are most important.

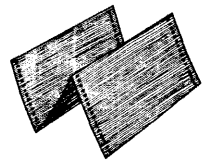
Among the outstanding features of PACE are its 8-bit or 16-bit data handling, exceptional data-processing throughput, compatibility with National's IMP-16 microprocessors, large variety of support chips, CPU and memory application cards for prototyping and production runs, a low-cost development system, and a sophisticated and more-powerful development system (which includes a full complement of software). Best of all PACE, family components are in volume production NOW.

National's IMP-16 Family









IMP-16, brother to PACE, is the most versatile of the 16-bit processors. Offering the user an expandable, bit-slice architecture and a variety of instruction sets, IMP-16 is uniquely suited to complex control, analysis, and data-reduction tasks.

Included in the IMP-16 family is the IMP-16P development system, which is supported by a full complement of software. Additionally available are CPU, memory, arithmetic, and input/output application cards.

National's IMP-16 microprocessors have been the forerunners of the industry and have proven their usefulness and applicability, in National's own DATACHECKER point-of-sale system, for example.

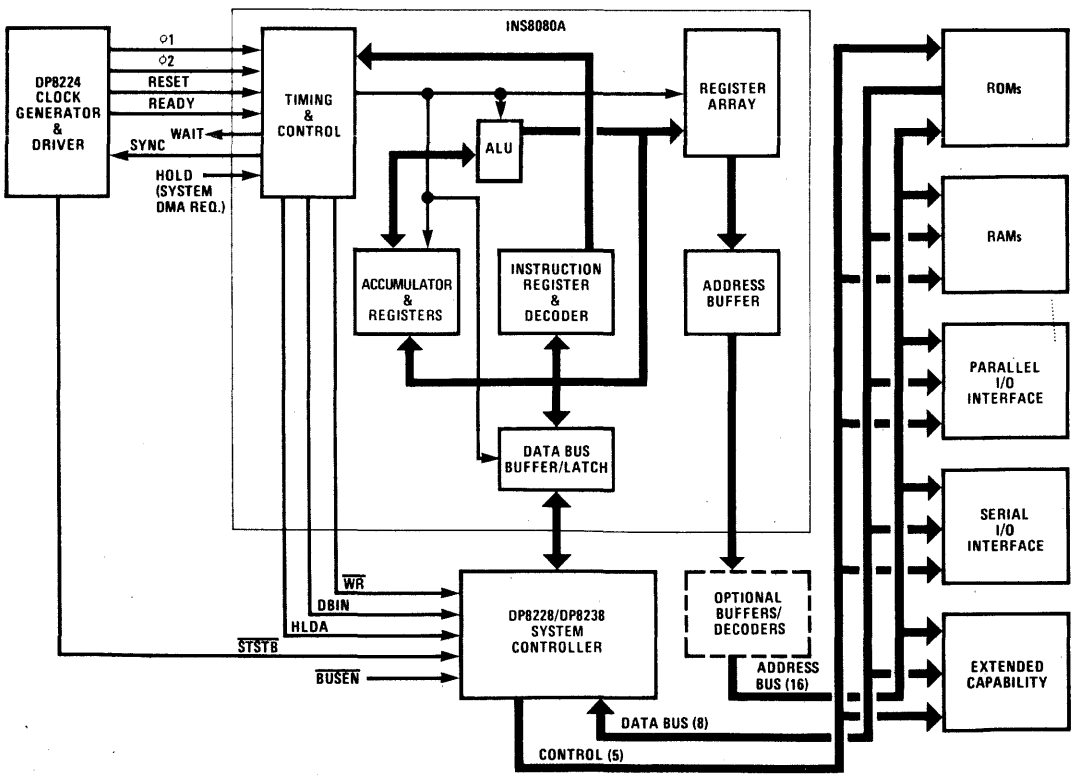
INS8080A 8-Bit N-Channel Microprocessor

general description

The INS8080A is an 8-bit microprocessor housed in a standard, 40-pin dual-in-line package. The chip, which is fabricated using N-channel silicon gate MOS technology, functions as the central processing unit (CPU) in National Semiconductor's N8080 microcomputer family.



The INS8080A has a 16-bit address bus that is capable of addressing up to 65k bytes of memory and up to 256 input and 256 output devices. Data is routed to and from the INS8080A on a separate bidirectional 8-bit bus. This data bus is also TRI-STATE®, making direct memory addressing (DMA) and multiprocessing applications possible. The INS8080A directly provides signals to control the interface to memory and I/O ports. All buses, including control, are TTL compatible.

An asynchronous interrupt capability is included in the INS8080A to allow external signals to change the instruction sequence. The interrupting device may vector the program to a particular service routine location (or some other direct function) by specifying an interrupt instruction to be executed.

features

- 2μs Instruction Cycle
- Variable Length Instructions
- General Purpose Registers – Six plus an Accumulator
- Direct Addressing up to 65k Bytes
- Variable Length Stack Accessed by 16-bit Stack Pointer
- Addresses 256 Input and 256 Output Ports
- Provisions for Vectored Interrupts
- TRI-STATE® Bus for DMA and Multiprocessing Capability
- TRI-STATE TTL Drive Capabilities for Address and Data Buses
- Decimal Arithmetic Capability
- Multiple Addressing Modes
  - Direct
  - Register
  - Register Indirect
  - Immediate
- Direct Plug-in Replacement for Intel 8080A

N8080A microcomputer family block diagram

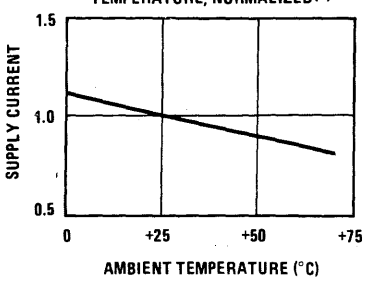
absolute maximum ratings

Temperature Under Bias . . . . . 0°C to +70°C
Storage Temperature . . . . . -65°C to +150°C
All Input or Output Voltages
with Respect to V_{BB} . . . . . -0.3V to +20V
V_{CC}, V_{DD} and V_{SS} with Respect to V_{BB} . . -0.3V to +20V
Power Dissipation 1.5W

Note: Maximum ratings indicate limits beyond which permanent damage may occur. Continuous operation at these limits is not intended and should be limited to those conditions specified under dc electrical characteristics.

dc electrical characteristics

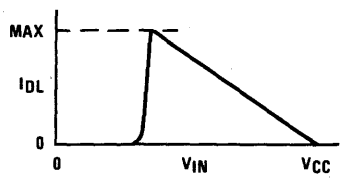
T_A = 0°C to +70°C, V_{DD} = +12V ± 5%, V_{CC} = +5V ± 5%, V_{BB} = -5V ± 5%, V_{SS} = 0V, unless otherwise noted.



Symbol	Parameter	Min.	Typ.	Max.	Unit	Test Condition
V_{ILC}	Clock Input Low Voltage	V_{SS}-1		V_{SS}+0.8	V	
V_{IHC}	Clock Input High Voltage	9.0		V_{DD}+1	V	
V_{IL}	Input Low Voltage	V_{SS}-1		V_{SS}+0.8	V	
V_{IH}	Input High Voltage	3.3		V_{CC}+1	V	
V_{OL}	Output Low Voltage			0.45	V	I_{OL} = 1.9mA on all outputs,
V_{OH}	Output High Voltage	3.7			V	I_{OH} = 150μA.
$I_{DD\,(AV)}$	Avg. Power Supply Current (V_{DD})		40	70	mA	Operation
$I_{CC\,(AV)}$	Avg. Power Supply Current (V_{CC})		60	80	mA	t_{CY} = 0.48μs
$I_{BB\,(AV)}$	Avg. Power Supply Current (V_{BB})		0.01	1	mA	
I_{IL}	Input Leakage			±10	μA	$V_{SS} \leq V_{IN} \leq V_{CC}$
I_{CL}	Clock Leakage			±10	μA	$V_{SS} \leq V_{CLOCK} \leq V_{DD}$
I_{DL}[2]	Data Bus Leakage in Input Mode			-100	μA	$V_{SS} \leq V_{IN} \leq V_{SS}$ + 0.8V
				-2.0	mA	V_{SS} + 0.8V $\leq V_{IN} \leq V_{CC}$
I_{FL}	Address and Data Bus Leakage			+10	μA	$V_{ADDR/DATA} = V_{CC}$
	During HOLD			-100	μA	$V_{ADDR/DATA} = V_{SS}$ + 0.45V

capacitance

T_A = 25°C, V_{CC} = V_{DD} = V_{SS} = 0V, V_{BB} = -5V

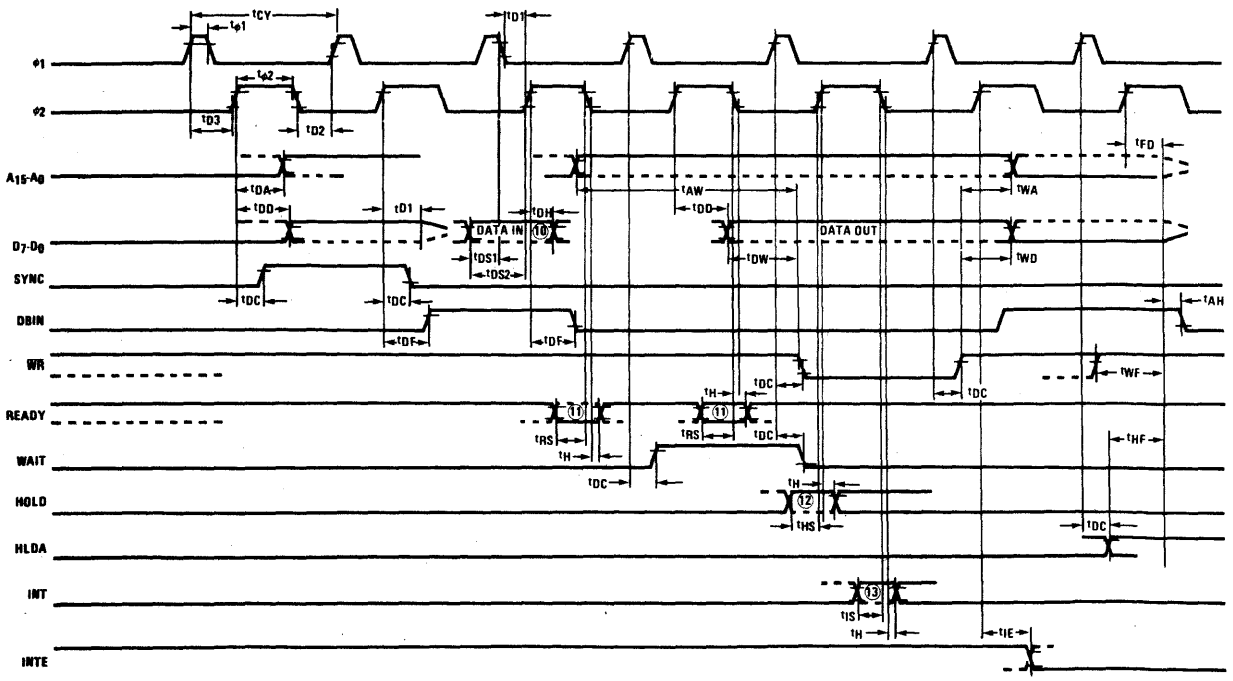


Symbol	Parameter	Typ.	Max.	Unit	Test Condition
C_ϕ	Clock Capacitance	17	25	pF	f_c = 1MHz
C_{IN}	Input Capacitance	6	10	pF	Unmeasured Pins
C_{OUT}	Output Capacitance	10	20	pF	Returned to V_{SS}

TYPICAL SUPPLY CURRENT VS. TEMPERATURE, NORMALIZED[3]

Notes:
1. The RESET signal must be active for a minimum of 3 clock cycles.
2. When DBIN is high and $V_{IN} > V_{IH}$ an internal active pullup will be switched onto the Data Bus.
3. ΔI supply / ΔT_A = -0.45%/°C.

DATA BUS CHARACTERISTIC DURING DBIN



©IC MASTER 1978

ac electrical characteristics

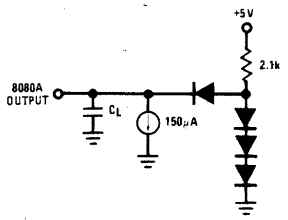
Symbol	Parameter	Min.	Max.	Unit	Test Condition
t_{CY} [3]	Clock Period	0.48	2.0	μs	
t_r, t_f	Clock Rise and Fall Time	0	50	ns	
$t_{\phi 1}$	ϕ_1 Pulse Width	60		ns	
$t_{\phi 2}$	ϕ_2 Pulse Width	220		ns	
t_{D1}	Delay ϕ_1 to ϕ_2	0		ns	
t_{D2}	Delay ϕ_2 to ϕ_1	70		ns	
t_{D3}	Delay ϕ_1 to ϕ_2 Leading Edges	80		ns	
t_{DA} [2]	Address Output Delay from ϕ_2		200	ns	C_L = 100pF
t_{DD} [2]	Data Output Delay from ϕ_2		220	ns	
t_{DC} [2]	Signal Output Delay from ϕ_1 or ϕ_2 (SYNC, $\overline{WR}$, WAIT, HLDA)		120	ns	C_L = 50pF
t_{DF} [2]	DBIN Delay from ϕ_2	25	140	ns	
t_{DI} [1]	Delay for Input Bus to Enter Input Mode		t_{DF}	ns	
t_{DS1}	Data Setup Time During ϕ_1 and DBIN	30		ns	

timing waveforms [14]

Note: Timing measurements are made at the following reference voltages: CLOCK '1' = 8.0V, '0' = 1.0V; INPUTS '1' = 3.3V, '0' = 0.8V; OUTPUTS '1' = 2.0V, '0' = 0.8V.

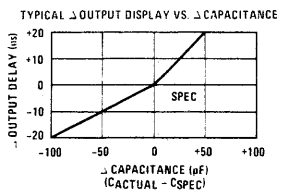
See notes on following page.

©IC MASTER 1978



ac electrical characteristics (cont'd.)

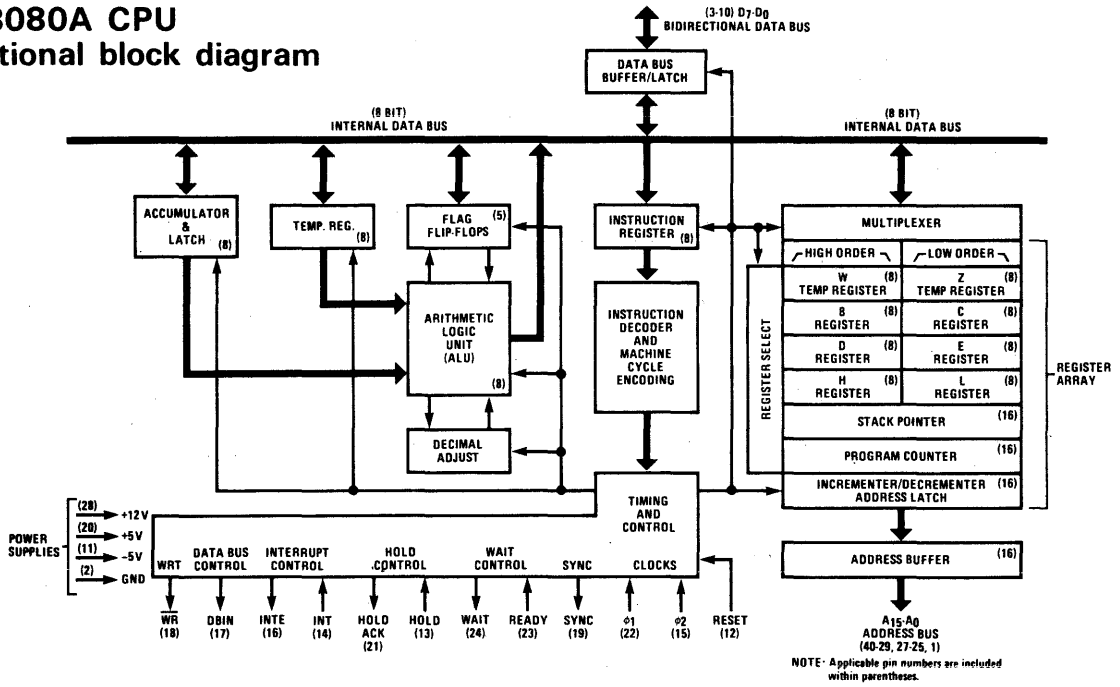
Symbol	Parameter	Min.	Max.	Unit	Test Condition
t_{DS2}	Data Setup Time to ϕ_2 During DBIN	150		ns	
t_{DH} [1]	Data Hold Time from ϕ_2 During DBIN	1		ns	
t_{IE} [2]	INTE Output Delay from ϕ_2		200	ns	C_L = 50pF
t_{RS}	READY Setup Time During ϕ_2	120		ns	
t_{HS}	HOLD Setup Time to ϕ_2	140		ns	
t_{IS}	INT Setup Time During ϕ_2 (During ϕ_1 in Halt Mode)	120		ns	
t_H	Hold Time from ϕ_2 (READY, INT, HOLD)	0		ns	
t_{FD}	Delay to Float During Hold (Address and Data Bus)		120	ns	
t_{AW} [2]	Address Stable Prior to $\overline{WR}$	5		ns	C_L = 100pF : Address, Data C_L = 50pF: $\overline{WR}$, HLDA, DBIN
t_{DW} [2]	Output Data Stable Prior to $\overline{WR}$	6		ns	
t_{WD} [2]	Output Data Stable from $\overline{WR}$	7		ns	
t_{WA} [2]	Address Stable from $\overline{WR}$	7		ns	
t_{HF} [2]	HLDA to Float Delay	8		ns	
t_{WF} [2]	$\overline{WR}$ to Float Delay	9		ns	
t_{AH} [2]	Address Hold Time After DBIN During HLDA	-20		ns	



Notes:

1. Data input should be enabled with DBIN status. No bus conflict can then occur and data hold time is assured. t_{DH} = 50ns or t_{DF}, whichever is less.

2. Typical load circuit:



3. $t_{CY} = t_{D3} + t_{r\phi2} + t_{\phi2} + t_{D2} + t_{f\phi2} + t_{r\phi1} \geq 480$ns.

4. The following are relevant when interfacing the INS8080A to devices having V_{IH} = 3.3V:
   a) Maximum output rise time from 0.8V to 3.3V = 100ns @ C_L = SPEC.
   b) Output Delay when measured to 3.0V = SPEC + 60ns @ C_L = SPEC.
   c) If $C_L \neq$ SPEC, add 0.6ns/pF if $C_L > C_{SPEC}$, subtract 0.3ns/pF (from modified delay) if $C_L < C_{SPEC}$.
5. $t_{AW} = 2t_{CY} - t_{D3} - t_{r\phi2} - 140$ns.
6. $t_{DW} = t_{CY} - t_{D3} - t_{r\phi2} - 170$ns.
7. If not HLDA, $t_{WD} = t_{WA} = t_{D3} + t_{r\phi2} + 10$ns. If HLDA, $t_{WD} = t_{WA} = t_{WF}$.
8. $t_{HF} = t_{D3} + t_{r\phi2} - 50$ns.
9. $t_{WF} = t_{D3} + t_{r\phi2} - 10$ns.
10. Data in must be stable for this period during DBIN · T_3. Both t_{DS1} and t_{DS2} must be satisfied.
11. Ready signal must be stable for this period during T_2 or T_W. (Must be externally synchronized.)
12. Hold signal must be stable for this period during T_2 or T_W when entering hold mode, and during T_3, T_4, T_5, and T_{WH} when in hold mode. (External synchronization is not required.)
13. Interrupt signal must be stable during this period of the last clock cycle of any instruction in order to be recognized on the following instruction. (External synchronization is not required.)
14. This timing diagram shows timing relationships only; it does not represent any specific machine cycle.

INS8080A CPU functional block diagram

INS8080A functional pin definition

The following describes the function of all of the INS8080A input/output pins. Some of these descriptions reference internal timing periods.

INPUT SIGNALS

Ready: When high (logic 1), indicates that valid memory or input data are available to the CPU on the INS8080A data bus. The READY signal is used to synchronize the CPU with slower memory or input/output devices. If the INS8080A does not receive a high READY input after sending out an address to memory or an input/output device, the INS8080A enters a WAIT mode for as long as the READY input remains low (logic 0). The CPU may also be single stepped by the use of the READY signal.

Hold: When high, requests that the CPU enter the HOLD mode. When the CPU is in the HOLD mode, the CPU address and data buses both will be in the high-impedance state. The HOLD mode allows an external device to gain control of the INS8080A address and data buses immediately following the completion of the current machine cycle by the CPU. The CPU acknowledges the HOLD mode via the HOLD ACKNOWLEDGE (HLDA) output line. The HOLD request is recognized under the following conditions:

- The CPU is in the HALT mode.
- The READY signal is active and the CPU is in the t_2 or t_W microcycle.

Interrupt (INT) Request: When high, the CPU recognizes an interrupt request on this line after completing the current instruction or while in the HALT mode. An interrupt request is not honored if the CPU is in the HOLD mode (HLDA = logic 1) or the Interrupt Enable Flip-flop is reset (INTE = logic 0).

Reset: When activated (high) for a minimum of three clock periods, the content of the Program Counter is cleared and the Interrupt Enable and Hold Acknowledge Flip-flops are reset. Following a RESET, program execution starts at memory location 0. It should be noted that the status flags, accumulator, stack pointer, and registers are not cleared during the RESET sequence.

ϕ_1 and ϕ_2 Clocks: Two non-TTL compatible clock phases which provide nonoverlapping timing references for internal storage elements and logic circuits of the CPU.

+12 Volts: V_{DD} Supply.

+5 Volts: V_{CC} Supply.

-5 Volts: V_{BB} Supply.

Ground: V_{SS} (0 volt) reference.

OUTPUT SIGNALS

Synchronizing (SYNC) Signal: When activated (high), the beginning of a new machine cycle is indicated and the status word is outputted on the Data Bus.

Address (A_{15} - A_0) Bus: This bus comprises sixteen TRI-STATE output lines. The bus provides the address to memory (up to 65k bytes) or denotes the input/output device number for up to 256 input and 256 output peripherals.

Wait: When high, acknowledges that the CPU is in the WAIT mode.

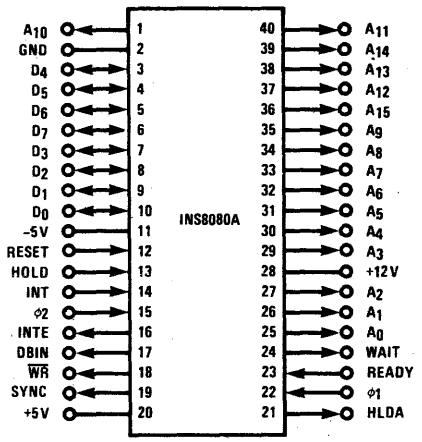
Write ($\overline{WR}$): When low, the data on the data bus are stable for WRITE memory or output operation.

Hold Acknowledge (HLDA): Goes high in response to a logic 1 on the HOLD line and indicates that the data and address bus will go to the high-impedance state. The HLDA begins at one of the following times:

- The t_3 microcycle of a READ memory input operation.
- The clock period following the t_3 microcycle of a WRITE memory output operation.

In both cases, the HLDA signal starts after the rising edge of the ϕ_1 clock, and high impedance occurs after the rising edge of the ϕ_2 clock.

©IC MASTER 1978



Interrupt Enable (INTE): Indicates the content of the internal Interrupt Enable Flip-flop. The Enable and Disable Interrupt (EI and DI) Instructions cause the Interrupt Enable Flip-flop to be set and reset, respectively. When the flip-flop is reset (INTE = logic 0), it inhibits interrupts from being accepted by the CPU. In addition, the Interrupt Enable Flip-flop is automatically reset (thereby disabling further interrupts) at the t_1 microcycle of the instruction fetch cycle, when an interrupt is accepted; it is also reset by the RESET Signal.

Data Bus In (DBIN): When high, indicates to external circuits that the data bus is in the input mode. The DBIN Signal should be used to gate data from memory or an I/O device onto the Data Bus.

INPUT/OUTPUT SIGNALS

Data ($D_7 - D_0$) Bus: This bus comprises eight TRI-STATE input/output lines. The bus provides bidirectional communication between the CPU, memory, and input/output devices for instructions and data transfers. A status word (which describes the current machine cycle) is also outputted on the data bus during the first microcycle of each machine cycle (SYNC = logic 1).

pin configuration

8080A status

Instructions for the 8080A require from one to five machine cycles for complete execution. The 8080A sends out 8 bits of status information on the data bus at the beginning of each machine cycle (during SYNC time). The following table defines the status information.

Status Information Definition

Symbols	Data Bus Bit	Definition
INTA*	D_0	Acknowledge signal for INTERRUPT request. Signal should be used to gate a restart instruction onto the data bus when DBIN is active.
$\overline{WO}$	D_1	Indicates that the operation in the current machine cycle will be a WRITE memory or OUTPUT function (WO = 0). Otherwise, a READ memory or INPUT operation will be executed.
STACK	D_2	Indicates that the address bus holds the pushdown stack address from the Stack Pointer.
HLTA	D_3	Acknowledge signal for HALT Instruction.
OUT	D_4	Indicates that the address bus contains the address of an output device and the data bus will contain the output data when WR is active.
M_1	D_5	Provides a signal to indicate that the CPU is in the fetch cycle for the first byte of an instuction.
INP*	D_6	Indicates that the address bus contains the address of an input device and the input data should be placed on the data bus when DBIN is active.
MEMR*	D_7	Designates that the data bus will be used for memory read data.

*These three status bits can be used to control the flow of data onto the INS8080A data bus.

Status Word Chart

Machine Cycle	Type	Data Bus Bit							
		D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0

condition flags and standard rules

There are five condition flags associated with the execution of instructions on the INS8080A. They are Zero, Sign, Parity, Carry, and Auxiliary Carry, and each flag is represented by a 1-bit register in the CPU. A flag is "set" by forcing the bit to 1, "reset" by forcing the bit to 0. The bit positions of the flags are indicated in the PUSH and POP PSW instructions.

Unless indicated otherwise, when an instruction affects a flag, it affects it in the following manner:

ZERO (Z): If the result of an instruction has the value 0, this flag is set; otherwise, it is reset.

SIGN (S): If the most significant bit of the result of the operation has the value 1, this flag is set; otherwise, it is reset.

PARITY (P): If the modulo 2 sum of the bits of the result of the operation is 0 (that is, if the result has even parity), this flag is set; otherwise, it is reset (that is, if the result has odd parity).

CARRY (CY): If the instruction resulted in a carry (from addition) or a borrow (from subtraction or a comparison) out of the high-order bit, this flag is set; otherwise, it is reset.

AUXILIARY CARRY (AC): If the instruction caused a carry out of bit 3 and into bit 4 of the resulting value, the auxiliary carry is set; otherwise, it is reset. This flag is affected by single-precision additions, subtractions, increments, decrements, comparisons, and logical operations; however, AC is used principally with additions and increments preceding a DAA (Decimal Adjust Accumulator) Instruction.

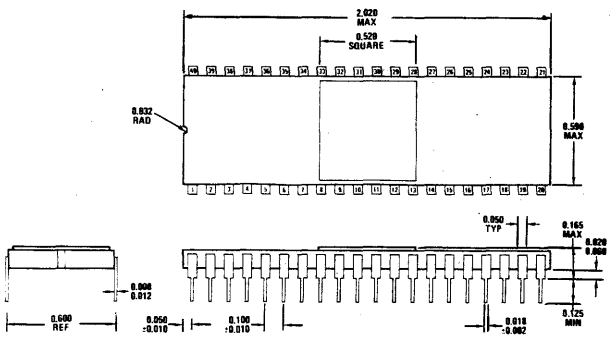
symbols and abbreviations

The following symbols and abbreviations are used in the subsequent description of the INS8080A instructions:



Symbols	Meaning
A	Register A (Accumulator)
B	Register B
C	Register C
D	Register D
H	Register H
L	Register L
DDD, SSS	The bit pattern designating one of the registers A, B, C, D, E, H, L (DDD = destination, SSS = source):

DDD or SSS	Register Name
111	A
000	B
001	C
010	D
011	E
100	H
101	L

byte 2	The second byte of the instruction
byte 3	The third byte of the instruction
port	8-bit address of an I/O device
r, r1, r2	One of the registers A, B, C, D, E, H, L

Symbols	Meaning
PC	16-bit program counter register (PCH and PCL are used to refer to the high-order and low-order 8 bits respectively.)
SP	16-bit stack pointer register (SPH and SPL are used to refer to the high-order and low-order 8 bits respectively.)
( )	The contents of the memory location or registers enclosed in the parentheses
←	"Is replaced by"
∧	Logical AND
∀	Exclusive OR
V	Inclusive OR
+	Addition
−	Twos complement subtraction
*	Multiplication
↔	"Exchange"
—	The ones complement (for example, $(\overline{A})$)
n	The restart number 0 through 7
NNN	The binary representation 000 through 111 for restart number 0 through 7 respectively
•	"Not affected"
0	"Reset"
1	"Set"
x	Unknown
↕	Flags affected according to Standard Rules

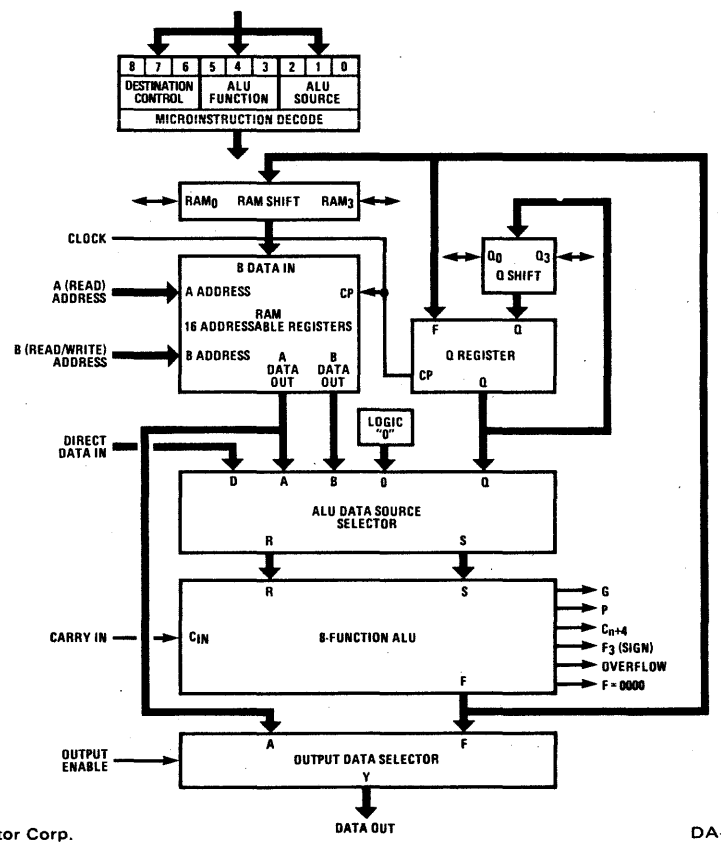
IDM2901A 4-Bit Bipolar Microprocessor

General Description



The IDM2901A 4-bit bipolar microprocessor slice is a cascadable device designed for use in Central Processing Units, programmable microprocessors, peripheral controllers, and other "high-speed" applications where economy, hardware/software flexibility, and easy expansion are system prerequisites. The building-block architecture and microinstruction format of the IDM2901A permits efficient emulation of most digital-based systems.

As shown in the simplified block diagram, the IDM2901A device consists of a 16-word by 4-bit 2-port RAM, a high-speed ALU, and the required shifting, decoding, and multiplexing circuits. The 9-bit microinstruction word is organized into three groups of three bits each – the first group (bits 0 - 2) selects ALU source operands, the second group (bits 3 - 5) selects the ALU function, and the last group (bits 6 - 8) selects the destination register within the ALU. The slice microprocessor is cascadable with full look-ahead or ripple carry; all outputs are TRI-STATE® and four status-flag outputs are available. To minimize power consumption and to maximize speed and reliability, the 40-pin LSI chip is fabricated using state-of-the-art (Low-Power Schottky) technology.

Features and Benefits

- **Multiple-address architecture** – improves system speed by providing simultaneous yet independent access to two working registers.
- **Multifunction ALU** – performs addition, two subtraction operations, and five logic functions on two source operands.
- **Flexible data-source selection** – for every ALU function, data is selected from five source ports for a total of 203 source operand pairs.
- **Left/right shift independent of ALU** – an arithmetic operation and a left or right shift can be obtained on the same machine cycle.
- **Four status flags** – carry, overflow, zero, and functional sign are available as outputs.
- **Expandable** – Connect any number of IDM2901As together for longer word lengths.
- **Microprogrammable** – three groups of 3 bits each for source operand, ALU function, and destination control.

				C_n			20	
I_I	Input High Current	V_{CC} = max; V_{IN} = 5.5 V					1.0	mA
I_{OZH}, I_{OZL}	Off State (High Impedance) Output Current	V_{CC} = max	$Y_0/Y_1/Y_2/Y_3$	V_O = 2.4 V			50	μA
				V_O = 0.5 V			−50	
			$RAM_{0,3}/Q_{0,3}$	V_O = 2.4 V (Note 4)			100	
				V_O = 0.5 V (Note 4)			−360	
I_{OS}	Output Short Circuit Current (Note 3)	V_{CC} = 5.75 V, V_O = 0.5 V	$Y_0/Y_1/Y_2/Y_3/G$		−30		−85	mA
			C_{n+4}		−30		−85	
			OVR/$\overline{P}$		−30		−85	
			F_3		−30		−85	
			$RAM_{0,3}/Q_{0,3}$		−30		−85	
I_{CC}	Power Supply Current (Note 6)	V_{CC} = max	T_A = 25°C			180	250	mA
			DC	T_A = 0°C to +70°C		180	265	
				T_A = +70°C		180	230	
			DM	T_C = −55°C to +125°C		180	280	
				T_C = +125°C		180	190	

Note 1: For conditions shown as min or max, use the appropriate value specified under Electrical Characteristics for the applicable device type.

Note 2: Typical limits are at V_{CC} = 5.0 V, 25° C ambient, and maximum loading.

Note 3: Not more than one output should be shorted at a time. Duration of the short circuit test should not exceed one second.

Note 4: These are TRI-STATE outputs internally connected to PNP inputs. Input characteristics are measured with $I_{6,7,8}$ in a state such that the TRI-STATE output is off (high-impedance).

Note 5: "Mil" = IDM2901A DM, FM; "Com'l" = IDM2901A DC, PC.

Note 6: Worst case I_{CC} is at minimum temperature.

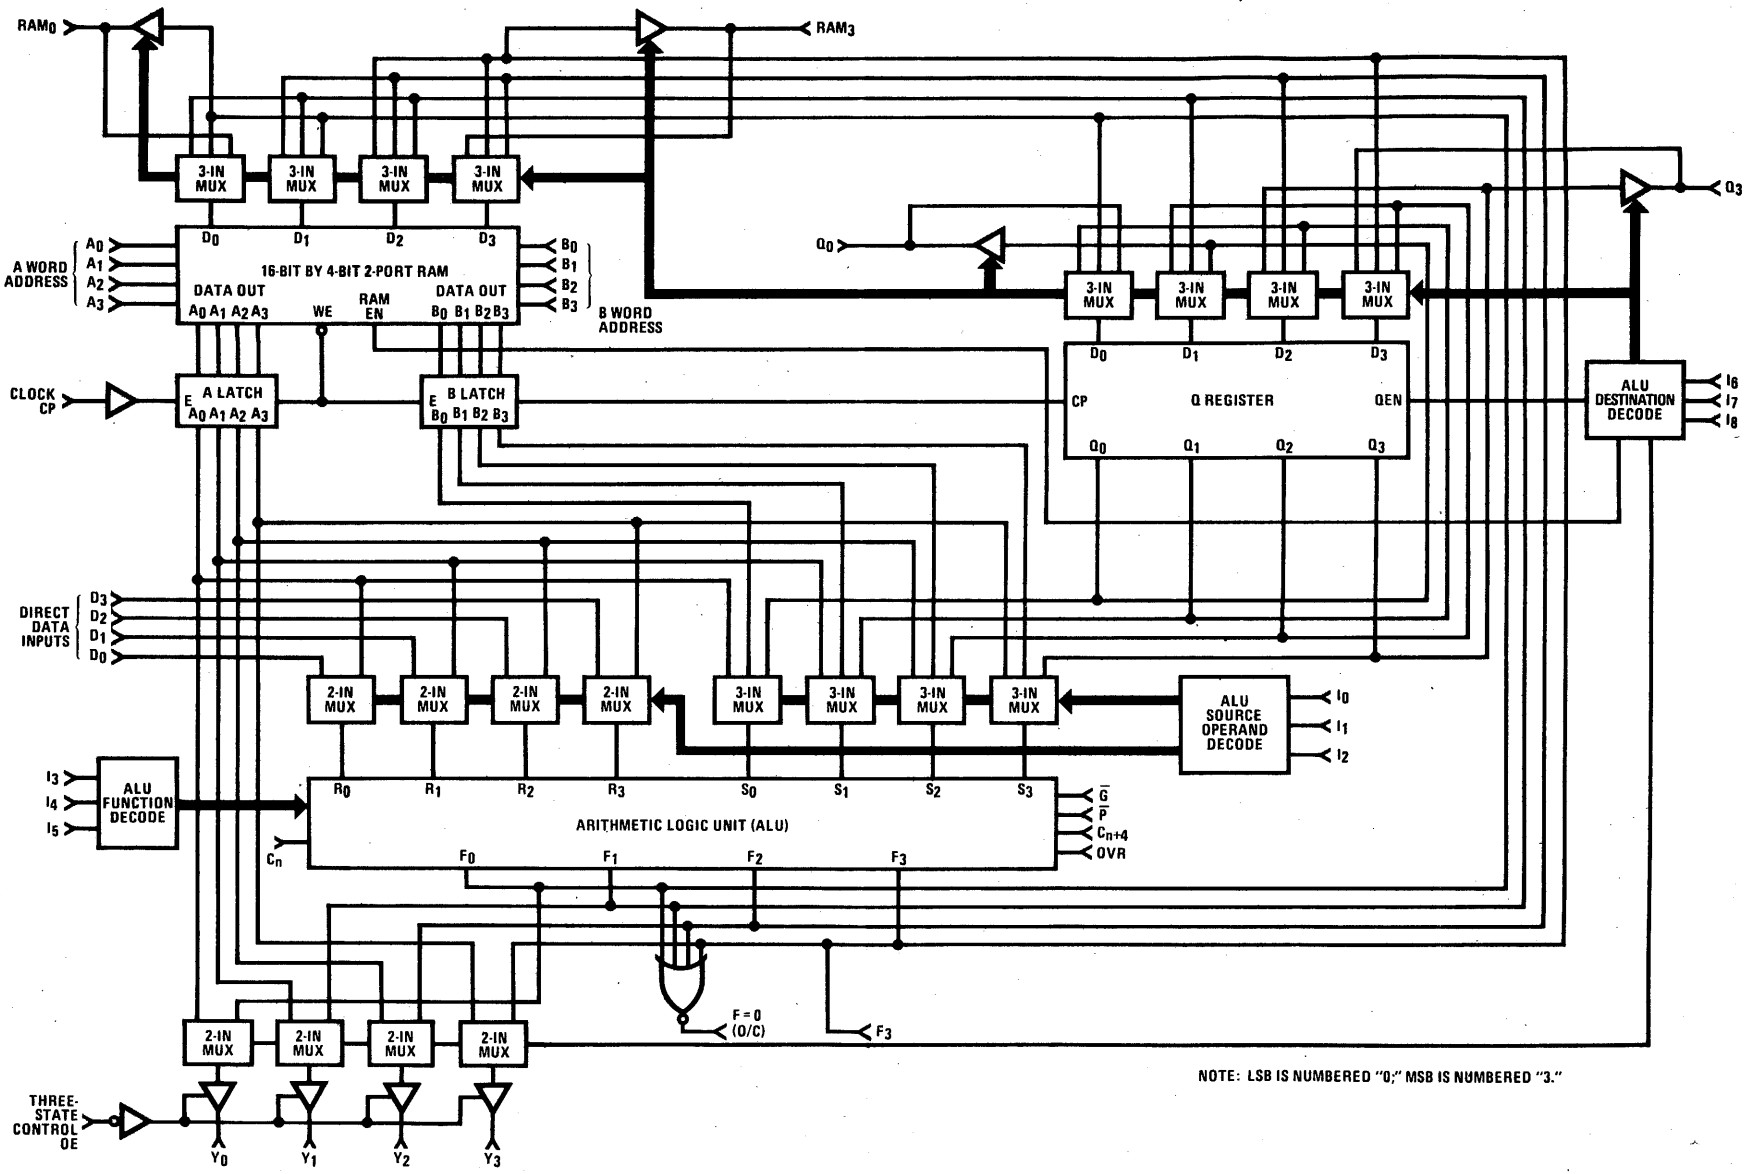

Figure 1. IDM2901A Microprocessor, Detailed Block Diagram

Figure 1 shows a detailed block diagram of the IDM2901A. Observe that all data paths are 4 bits wide; however, the 4-bit slice can be cascaded to the number of bits required for a particular application. Although all parts of the bipolar device are important, the two key elements are the 16-word by 4-bit 2-port RAM and the high-speed ALU.

Any one of the 16 words in RAM can be read from the A-port (A_3-A_0) or the B-port (B_3-B_0); the selected word for the A-port is determined by the 4-bit A-address field, whereas the B-address field controls the output of the B-port. If the two address codes are identical, the same file data appears simultaneously at both output ports (A and B).

When enabled by RAM EN, new data is written into the file "word" defined by the B-address field; the write function is implemented when the clock input is low.

Each bit of data to be written is input via a 3-input multiplexer; this scheme permits shifting up one bit position (from LSB towards MSB), shifting down one bit position (from MSB towards LSB), or not shifting at all. A similar scheme is used when data is written into the "Q" register.

Each of the A and B data ports drives an associated 4-bit latch. These latches hold the RAM data while the clock input is low; consequently, any possibility of race conditions when writing new data is eliminated.

The high-speed ALU can perform three binary arithmetic and five logic operations on the two 4-bit input words (R_3-R_0 and S_3-S_0). The R-input field is driven from a 2-input multiplexer, whereas the S-input field is driven by a 3-input multiplexer. Both the R- and S-multiplexers have an inhibit capability, where no data is passed – this is equivalent to a "zero" source operand. Referring to figure 1, observe that the A-port output of the RAM and the 4-bit direct-data inputs (D_3-D_0) are connected to the R-input multiplexers; the S-input multiplexer has three inputs – one from the A-port of RAM, one from the B-port of RAM, and one from the Q-register.

With the foregoing input-multiplexer scheme, the inputs (A, B, D, Q, and "Zero"), when taken in pairs, provide any one of ten source operands for the ALU – AB, AD, AQ, A0, BD, BQ, B0, DQ, D0, and Q0. When the A and B address fields for RAM are identical, it is clear that certain combinations (AD/BD, AQ/BQ, and A0/B0) are redundant; that is, the identical function is implemented for either operand. Only seven of the combinations are completely nonredundant. Eight of the ten combinations (source operands) are implemented by the IDM2901A microprocessor. The ALU source operands are selected by three microinstruction inputs – I_0, I_1, and I_2. These inputs are defined in figure 2. Each of the preceding D and Q operands provides an essential function. The D input (direct-data) is used to load the working registers inside the 2901 device; also, this input source can be used to modify data files within the ALU. The Q-register is an internal 4-bit data source that is well suited for a multiply/divide operation; however, for some applications, it can be used as a data-holding register or as an accumulator.

The ALU is a high-speed arithmetic/logic operator that is capable of performing three binary arithmetic functions and five logic functions. Three microinstruction inputs (I_3, I_4, and I_5) are used to select one of the eight functions; these inputs, along with their octal codes, are defined in figure 3.

Micro Code				ALU Source Operands	
I_2	I_1	I_0	Octal Code	R	S
L	L	L	0	A	Q
L	L	H	1	A	B
L	H	L	2	O	Q
L	H	H	3	O	B
H	L	L	4	O	A
H	L	H	5	D	A
H	H	L	6	D	Q
H	H	H	7	D	O

Figure 2. ALU Source Operand Control

H	H	H	7	R EX-NOR S	$\overline{R \veebar S}$

Figure 3. ALU Function Control

©IC MASTER 1978

Normally, the look-ahead carry mode is used when cascading the ALUs of several microprocessor devices. The carry generate ($\overline{G}$) and carry propagate ($\overline{P}$) outputs are suitable for use in a carry-look-ahead generator. A carry-out (C_{n+4}) is also generated and is available for use as the carry flag in a status register or as a ripple-carry output. Both carry-in (C_n) and carry-out (C_{n+4}) are active-high signals. Three other status-oriented outputs are available from the ALU; these are F_3, F = 0, and overflow (OVR). The F_3 output is the most significant (sign) bit of the ALU, and, without enabling the TRI-STATE outputs, it can be used to determine positive or negative results. When enabled, the logic level of F_3 is identical to that of sign bit Y_3. The F = 0 output is used for zero detect; F = 0 is high when all F outputs are low. The F = 0 output is of the open-collector type and can be wire ORed between microprocessor slices. The overflow (OVR) output is used to flag arithmetic operations that exceed the available twos-complement number range. When an overflow exists (C_{n+3} and C_{n+4} are of opposite polarity), the OVR output is high.

Outputs from the ALU can be stored in the register file or the Q register, or can be transmitted to the outside world. Eight possible destination codes are defined by microinstruction inputs I_6, I_7, and I_8; the various destination control codes are shown in figure 4. The 4-bit data field (Y_3-Y_0) is a TRI-STATE output that can be directly bus organized. The Y outputs are enabled by $\overline{OE}$; when this control signal is high, the Y-outputs are TRI-STATEd. A 2-input multiplexer is also used at the Y-output port to select either the A port of RAM or the F output of the ALU; this selection is controlled by the previously described microinstruction inputs (I_6, I_7, and I_8).

As previously described, the RAM inputs (register file) are driven by a 3-input multiplexer. Thus, outputs from the ALU can be entered nonshifted, shifted up (towards MSB) one position (x 2), or shifted down (towards LSB) one position (÷ 2). The shifter is equipped with two ports — RAM_0 and RAM_3; both ports consist of a TRI-STATE buffer-driver, each of which supplies one input to the foregoing multiplexer. In the shift-up (x 2) mode, the RAM_3 output driver and the RAM_0 multiplexer input are enabled, whereas in the shift-down (÷ 2) mode, the RAM_0 output driver and RAM_3 multiplexer input are enabled; in the no-shift mode, both drivers are TRI-STATE and neither multiplexer input is enabled. The shifter is controlled by the I_6, I_7, and I_8 microinstruction inputs.

The Q register likewise is driven from a 3-input multiplexer and the Q shifter is equipped with two input/output ports — Q_0 and Q_3. Operation of these two ports is similar to that of the RAM shifter, and the ports are controlled by I_6, I_7, and I_8. In the shift-up or shift-down modes, the Q register is shifted in a specified direction with the input/output terminals of the register being an input (for a shift-up) or an output (for a shift-down). In the no-shift mode, the multiplexer may enter the ALU data into the Q register; in this case, input/output lines of the register are TRI-STATE.

The clock input shown in figure 1 controls the RAM, the A and B latches, and the Q register. When the clock input is high, the A and B latches are open and data from the RAM outputs is allowed to pass through to the ALU or "Y" outputs. When the clock input is low, both latches are closed and the last data entered is retained. When the clock input is low and if the input control code (I_6, I_7, and I_8) has enabled a file-write operation, new data, as defined by the 4-bit B-address field, is written into the RAM file. When enabled, data is clocked into the Q register on the low-to-high transition of the clock pulse.

Source Operands and ALU Functions

Any one of eight source operand pairs can be selected by instruction inputs I_0, I_1, and I_2 for use by the ALU; instruction inputs I_3, I_4, and I_5 then control function selection for the ALU — five logic and three arithmetic functions. In the arithmetic mode, the carry input (C_n) also affects the ALU functions; the carry input has no effect on the "F" result in the logic mode. These control parameters (I_6-I_0 and C_n) are summarized in figure 5 to completely define the ALU/source operand functions.

The ALU functions can also be examined on a task basis: that is, add, subtract, AND, OR, and so on. Again, in the arithmetic mode, the carry input will affect the result, whereas in the logic mode it will not. Figures 6 and 7, respectively, define the various logic and arithmetic functions of the ALU; both carry states ($C_n = 0/C_n = 1$) are defined in the function matrices.

Figure 4. ALU Destination Control

Micro Code				RAM Function		Q-Reg. Function		Y Output	RAM Shifter		Q Shifter	
I_8	I_7	I_6	Octal Code	Shift	Load	Shift	Load		RAM_0	RAM_3	Q_0	Q_3

Logic Functions for G, P, Cn+4, and OVR

When the IDM2901A is in the add or the subtract mode, four signals (G, P, C_{n+4}, and OVR) are available to indicate carry and overflow conditions. Based on the eight ALU functions, logic equations for these signals are as follows. (Note: The "R" and "S" inputs are selected according to figure 2.)

Definitions (+ = OR):

$P_0 = R_0 + S_0$ $\quad G_0 = R_0S_0$

$P_1 = R_1 + S_1$ $\quad G_1 = R_1S_1$

$P_2 = R_2 + S_2$ $\quad G_2 = R_2S_2$

$P_3 = R_3 + S_3$ $\quad G_3 = R_3S_3$

$C_4 = G_3 + P_3G_2 + P_3P_2G_1 + P_3P_2P_1G_0 + P_3P_2P_1P_0C_n$

$C_3 = G_2 + P_2G_1 + P_2P_1G_0 + P_2P_1P_0C_n$

Pinout Descriptions of IDM 2901A

Pin functions for the IDM2901A 4-bit slice microprocessor are as follows:

$A_3 - A_0$ 4-bit address field used to select one of the file registers whose contents are displayed through the A port of RAM.

$B_3 - B_0$ 4-bit address field used to select one of the file registers whose contents are displayed through the B port of RAM. When the clock is low, new data can be written into the selected B-port register.

$I_8 - I_0$ Nine instruction-control lines — $I_0/I_1/I_2$ determine data sources of ALU, $I_3/I_4/I_5$ select ALU function, and $I_6/I_7/I_8$ select data inputs for the Q register or the register file.

Q_3/RAM_3 Serves as shift data input/output lines for the most significant bit (MSB) of Q register (Q_3) and the register stack (RAM_3). These lines are TRI-STATE outputs that connect to TTL inputs within the IDM2901A device. When the destination code, as defined by $I_6/I_7/I_8$, indicates an up-shift (octal 6 or 7), the TRI-STATE outputs are enabled; accordingly, the MSB of the Q register is available on the Q_3 pin and the MSB of the ALU output is available on the RAM_3 pin. Otherwise, these output lines are TRI-STATE or serve as LS-TTL inputs. When a down-shift is indicated by the destination code, the Q_3 and RAM_3 pins are used as data inputs to the MSB of the Q register or RAM.

Q_0/RAM_0 These shift lines are similar to Q_3 and RAM_3, except they operate on the least significant bit (LSB) of the Q register and RAM. To transfer data for up- and down-shifts of the Q register and the ALU, the Q_0 and RAM_0 pins are connected, respectively, to the next less-significant device (Q_n and RAM_n) in the cascaded chain.

$D_3 - D_0$ A 4-bit data field that can be selected as a source of external data for ALU — D_0 is the least significant bit.

$Y_3 - Y_0$ 4-bit output data of IDM2901A. These lines are TRI-STATE; when enabled, they provide either the ALU output or data from the A port of the register file — the selected source is determined by the destination code, as defined by I_6, I_7, and I_8.

$\overline{OE}$ When the Output Enable ($\overline{OE}$) signal is high, the Y outputs are inactive; when the signal is active-low, the active high or low outputs are enabled.

$\overline{P}/\overline{G}$ Carry generate and propagate outputs — see figure 8 for logic equations.

OVR The overflow flag corresponds to the exclusive-OR of the carry-in and carry-out of the MSB of the ALU. When set high, it indicates that the result of an arithmetic twos-complement operation has overflowed into the sign bit — see figure 8 for the logic equation.

F = 0 An open-collector output that goes high if all data lines ($F_3 - F_0$) are low, that is, the result of an ALU operation is zero.

C_n Carry-in to ALU.

C_{n+4} Carry-out of ALU — see figure 8 for logic equations.

CP Clock input. Outputs of Q register and file are clocked on low-to-high transition; the low interval of the clock input corresponds to the "write enable" period of the 16-by-4 RAM, that is, the "master" latches of the register file. When the clock is low, the output latches store the data previously held at the RAM outputs; thus, synchronous master-slave operation of the register file is permitted.

F_3 Most significant (sign) bit output of the ALU.

$I_{5,4,3}$	Function	$\overline{P}$	$\overline{G}$	C_{n+4}	OVR
0	R + S	$\overline{P_3P_2P_1P_0}$	$\overline{G_3 + P_3G_2 + P_3P_2G_1 + P_3P_2P_1G_0}$	C_4	$C_3 \forall C_4$
1	S − R	Same as R + S equations, but substitute $\overline{R_i}$ for R_i in definitions.			
2	R − S	Same as R + S equations, but substitute $\overline{S_i}$ for S_i in definitions.

Guaranteed Operating Conditions Over Temperature and Voltage

When operated in a system, the timing requirements for the IDM2901A are defined in tables 1, 2, and 3. Table 1 provides clock characteristics of the IDM2901A, table 2 gives the combinational delay times from input to output, and table 3 specifies setup and hold times. If used according to the specified delay and setup times, the device is guaranteed to function properly over the entire operating range. Table 3 defines the time prior to the end of the cycle (low-to-high transition of clock pulse) that each input must be stable to guarantee that the correct data is written into one of the internal registers.

Table 1. Cycle Time and Clock Characteristics

Time	IDM2901A	
	DC, PC	DM, FM
Read-Modify-Write Cycle (time from selection of A, B registers to end of cycle)	60 ns	75 ns
Maximum Clock Frequency to Shift Q Register (50% duty cycle)	20 MHz	16 MHz
Minimum Clock Low Time	25 ns	30 ns
Minimum Clock High Time	25 ns	30 ns
Minimum Clock Period	60 ns	75 ns

Table 2. Maximum Combinational Propagation Delays (all in ns; $C_L \leq 50$ pF)

Table 3. Setup and Hold Times (all in ns) — Note 1

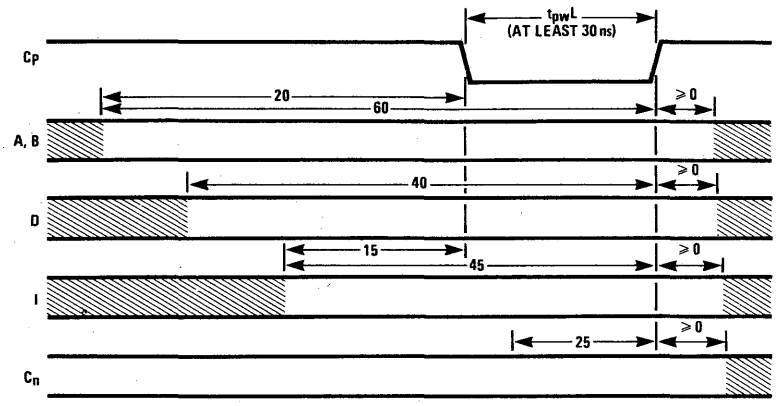
		Commercial IDM2901A DC, PC (0°C to +70°C, 5 V ± 5%)		Military IDM2901A DM, FM (−55°C to +125°C, 5 V ± 10%)	
From Input	Notes	Setup Time	Hold Time	Setup Time	Hold Time
A, B Source	2, 3, 4, 5	60, $t_{pw}L$ + 20	0	75, $t_{pw}L$ + 25	0
B Destination	2, 4	$t_{pw}L$ + 15	0	$t_{pw}L$ + 15	0
D (arithmetic mode)		40	0	50	0
D (I = X37)	5	40	0	50	0
C_n		25	0	30	0
$I_{2,1,0}$		45	0	55	0
$I_{5,4,3}$		45	0	55	0
$I_{8,7,6}$	4	$t_{pw}L$ + 15	0	$t_{pw}L$ + 15	0
$RAM_{0,3}/Q_{0,3}$		20	0	25	0

Note 1: See figures 9 and 10.

Note 2: If the B address is used as a source operand, allow for the "A, B Source" setup time; if it is used only for the destination address, use the "B Destination" setup time.

Note 3: Where two numbers are shown, both must be met.

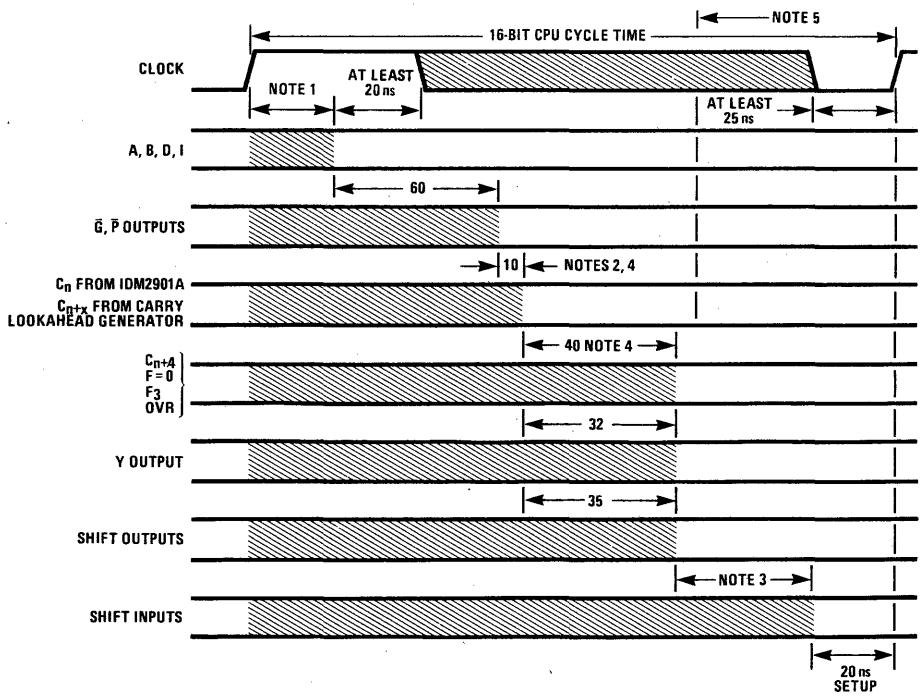
Note 4: "$t_{pw}L$" is the clock low time.



Note 5: DVO is the fastest way to load the RAM from the D inputs. This function is obtained with I = 337.

Note 6: Using Q register as source operand in arithmetic mode. Clock is not normally in critical speed path when Q is not a source.

©IC MASTER 1978



Set-Up and Hold Times (mimimum cycles from each input)

Setup and hold times are defined relative to the low-to-high transition of the clock pulse. At all times, inputs must be stable from the setup time prior to the clock until the hold time after the clock – observe that all hold times are "zero." The set-up times allow sufficient time to perform the correct operation on the correct data so that the correct ALU data can be written into the correct register.

Note: Numbers shown are minimum data-stable times in nanoseconds for commercial product – see table 3 for detailed information.

Figure 9. Setup Times for Input Parameters of IDM2901A

Notes:

1. This delay is the max t_{pd} of the register containing A, B, D, and I.
2. 10 ns for look-ahead carry. For ripple carry over 16 bits use 2 x ($C_n \rightarrow C_{n+4}$), or 60 ns.
3. This is the delay associated with the multiplexer between the shift outputs and the shift inputs on the IDM2901A.
4. Not applicable for logic operations.
5. Clock rising edge may occur here if add and shift do not occur on same cycle.

Figure 10. Switching Waveforms for 16-Bit System Assuming A, B, D, and I are Driven from Registers with the Same Propagation Delay and Clocked by the IDM2901A. (These are maximum times in nanoseconds using commercial-product specifications.)

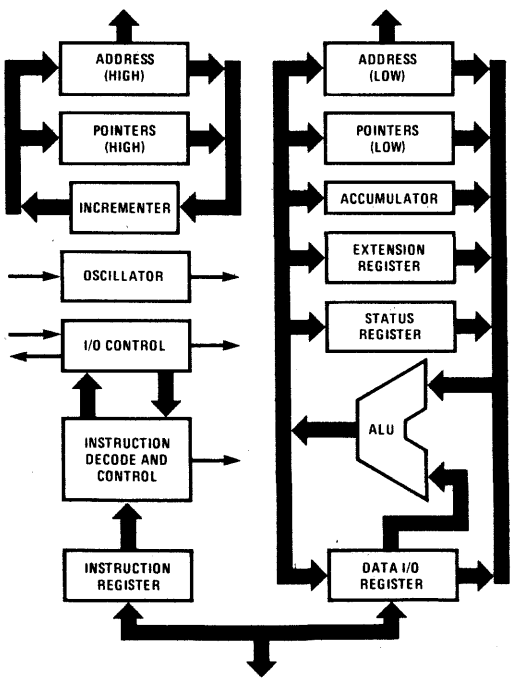
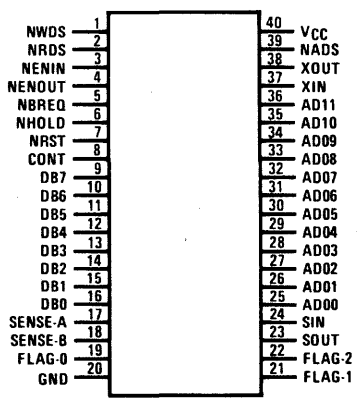
ISP-8A/600 single-chip 8-bit n-channel microprocessor (SC/MP-II)

general description

SC/MP (Simple Cost-effective MicroProcessor) is a single-chip 8-bit microprocessor packaged in a standard, 40-pin, dual-in-line package.



N-channel, silicon gate, depletion mode standard-process technology ensures high performance, high reliability, and high producibility.



SC/MP is intended for use in general-purpose applications where cost per function is a most significant criterion. But cost efficiency is only a part of SC/MP's story. It goes on to include a variety of useful functions that are not even provided by some of the expensive microprocessors, like self-contained timing circuitry, 16-bit (65k) addressing capability, serial or parallel data-transfer capability and common memory/peripheral instructions. The built-in features in conjunction with the low initial cost describe what SC/MP really is — a microprocessor specifically designed to provide the simplest and most efficient solution to many application requirements.

customer benefits

- Simpler interfacing
  - Bidirectional TRI-STATE® 8-bit data bus
  - TTL-compatible input/output interface
- Si-gate N-channel ion-implant process
- Direct Memory Access (DMA) and multiprocessor capabilities
  - Handshake bus-access control on chip
- Simplified programming
  - Multiple addressing modes — program-counter-relative, immediate data, indexed, auto-indexed, and implied
- Direct control output
  - Three user-accessible control-flag outputs
- Simpler I/O hardware
  - Separate serial-data input and output ports
  - Two sense inputs
  - Direct interfacing to standard memory parts
- Simplified timing hardware
  - On-chip clock generator
- Interface flexibility
  - Capability to interface with memories or peripherals of any speed
- Large system capability
  - Address capability to 65k bytes of memory
- Simplified power requirements
  - Single 5-volt supply
  - Low power
- Lower cost
  - Plastic package

functional description

SC/MP is a self-contained general-purpose microprocessor designed for ease of implementation in stand-alone, DMA (Direct Memory Access), and multiprocessor applications. Communications between SC/MP and external memory/peripheral devices are effected via a 12-bit dedicated address bus and an 8-bit bidirectional data bus. During the address interval of each input/output cycle, SC/MP employs both busses to provide a 16-bit address output: the 12 least significant address bits are sent out over the 12-bit address bus and the 4 most significant address bits are sent out over the 8-bit data bus along with 4 status bits. Separate strobe outputs from SC/MP (NADS, NWDS, NRDS) indicate when valid address information is present on the two busses, and when valid input/output memory or peripheral data are present on the 8-bit bus. To further extend flexibility of application, serial data input/output ports are also provided so that serial data transfers can be effected under program control. The remaining input/output signals shown in figure 1 are dedicated to general-purpose control and status functions, including initialization, bus management, microprocessor halt, interrupt request, input/output cycle extension, and user-specified hardware/software interface functions. A detailed description of each input/output signal is provided in table 1.

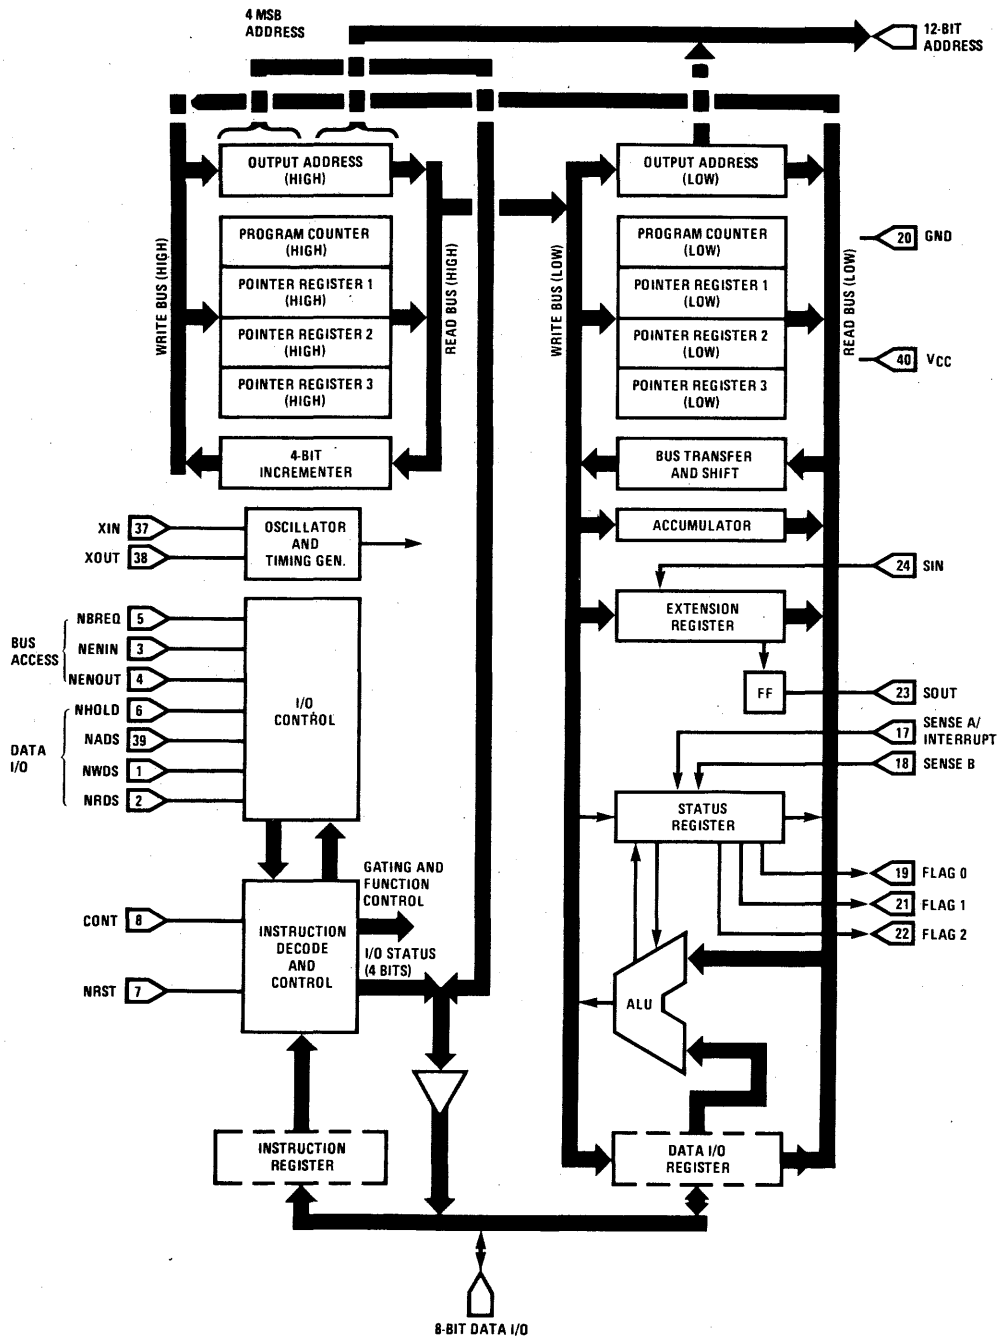

FIGURE 1. SC/MP-II Detailed Block Diagram

©IC MASTER 1978

TABLE 1. Input/Output Signal Description

Signal Mnemonic	Functional Name	Description
NRST	Reset Input	Set high for normal operation. When set low, aborts in-process operations. When returned high, internal control circuit zeroes all programmer-accessible registers; then, first instruction is fetched from memory location 0001_{16}.
CONT	Continue Input	When set high, enables normal execution of program stored in external memory. When set low, SC/MP operation is suspended (after completion of current instruction) without loss of internal status.
NBREQ	Bus Request Input/Output	Associated with SC/MP internal allocation logic for system bus. Can be used as bus request output or bus busy input. Requires external load resistor to V_{CC}.
NENIN	Enable Input	Associated with SC/MP internal allocation logic for system bus. When set low, SC/MP is granted access to system busses. When set high, places system busses in high-impedance (TRI-STATE®) mode.
NENOUT	Enable Output	Associated with SC/MP internal allocation logic for system bus. Set low when NENIN is low and SC/MP is not using system busses (NBREQ-high). Set high at all other times.
NADS	Address Strobe Output	Active-low strobe. While low, indicates that valid address and status output are present on system busses.
NRDS	Read Strobe Output	Active-low strobe. On trailing edge, data are input to SC/MP from 8-bit bidirectional data bus. High-impedance (TRI-STATE®) output when input/output cycle is not in progress.
NWDS	Write Strobe Output	Active-low strobe. While low, indicates that valid output data are present on 8-bit bidirectional data bus. High-impedance (TRI-STATE®) output when input/output cycle not in progress.
NHOLD	Input/Output Cycle Extend Input	When set low prior to trailing edge of NRDS or NWDS strobe, stretches strobe to extend input/output cycle; that is, strobe is held low until NHOLD signal is returned high.
SENSE A	Sense/Interrupt Request Input	Serves as interrupt request input when SC/MP internal IE (Interrupt Enable) flag is set. When IE flag is reset, serves as user-designated sense condition input. Sense condition testing is effected by copying status register to accumulator.
SENSE B	Sense Input	User-designated sense-condition input. Sense-condition testing is effected by copying status register to accumulator.
SIN	Serial Input to E Register	Under software control, data on this line are right-shifted into E register by execution of SIO instruction.
SOUT	Serial Output from E Register	Under software control, data are right-shifted onto this line from E register by execution of SIO instruction. Each data bit remains latched until execution of next SIO instruction.
FLAGS 0, 1, 2	Flag Outputs	User-designated general-purpose flag outputs of status register. Under program control, flags can be set and reset by copying accumulator to status register.
AD00-AD11	Address Bit 00 through Address Bit 11	Twelve TRI-STATE® address output lines. SC/MP outputs 12 least significant address bits on this bus when NADS strobe is low. Address bits are then held valid until trailing edge of read (NRDS) or write (NWDS) strobes. After trailing edge of NRDS or NWDS strobe, bus is set to high-impedance (TRI-STATE®) mode until next NADS strobe.

NOTE:

The 8-bit bidirectional data bus is set to the high-impedance (TRI-STATE®) mode except when it is actually in use by SC/MP (NADS, NRDS, or NWDS low). During the addressing interval of each input/output cycle (NADS low), SC/MP provides address and status outputs over the bus; during the ensuing data-transfer interval (NRDS or NWDS low), 8-bit input or output data bytes are routed over the bus.

TABLE 1. Input/Output Signal Description (Continued)

Signal Mnemonic/ Pin Designation	Output at NADS Time		Input at NRDS Time	Output at NWDS Time
	Functional Name	Description		
DB0	Address Bit 12	Fourth most significant bit of 16-bit address.	Input data are expected on the eight (DB0-DB7) lines.	Output data are valid on the eight (DB0-DB7) lines.
DB1	Address Bit 13	Third most significant bit of 16-bit address.		
DB2	Address Bit 14	Second most significant bit of 16-bit address.		
DB3	Address Bit 15	Most significant bit of 16-bit address.		
DB4	R-Flag	When high, data input cycle is starting; when low, data output cycle is starting.		
DB5	I-Flag	When high, first byte of instruction is being fetched.		
DB6	D-Flag	When high, indicates delay cycle is starting; that is, second byte of DLY instruction is being fetched.		
DB7	H-Flag	When high, indicates that Halt Instruction has been executed. (In some system configurations, the H-Flag output is latched and, in conjunction with the CONTinue input, provides a programmed halt.)	**Note:** The DB0 through DB7 (AD12-HFLG) lines are a high-impedance (open circuit) load when SC/MP does not have access to the input/output bus.	

DRIVERS AND RECEIVERS

Equivalent circuits for SC/MP drivers and receivers are shown below. All inputs have static charge protection circuits consisting of an RC filter and voltage clamp. These devices still should be handled with care, as the protection circuits can be destroyed by excessive static charge.

SC/MP-II Driver and Receiver Equivalent Circuits

TIMING CONTROL

All necessary timing signals are provided by a three-stage inverter ring oscillator contained on the SC/MP chip. Two control pins, XIN and XOUT, permit the frequency of the oscillator to be controlled by any of the following methods:

1. By leaving the XOUT pin unterminated and driving the XIN pin with an externally generated TTL clock that conforms to the parameters shown in figure 2A. For this method, the frequency of the oscillator is equal to the frequency of the external clock input.

2. By connecting a resistor-capacitor feedback network between the XIN and XOUT pins and GND as shown in figure 2B.

3. By connecting a crystal with low-pass filter network between the XIN and XOUT pins and GND as shown in figure 2C (for above 1 megahertz) or figure 2D (for 1 megahertz or below). For this method, the frequency of the oscillator is equal to the resonant frequency of the crystal and the low-pass filter prevents unwanted harmonic oscillations.

In addition to illustrating appropriate frequency-control networks for the on-chip oscillator, figures 2A through 2D also show how an optional driver may be used to derive a system clock from the oscillator signal present at the XOUT pin. For reference purposes, the timing relationship between the XOUT signal and the NADS strobe is shown in figure 3.

In the discussions that follow, instruction execution and input/output timing are described in terms of microcycles.

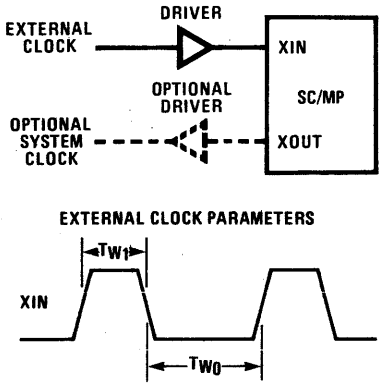
©IC MASTER 1978

The time interval of a microcycle is four times the period of the oscillator; that is:

period of one microcycle = $2T_C$

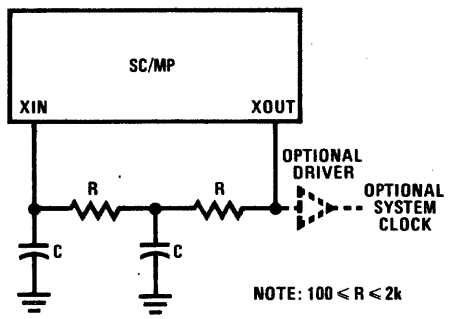
$$T_C = 2(\frac{1}{f_{osc}}) = 2(\frac{1}{f_{res}}) = 2(\frac{1}{f_{XIN}})$$

where:



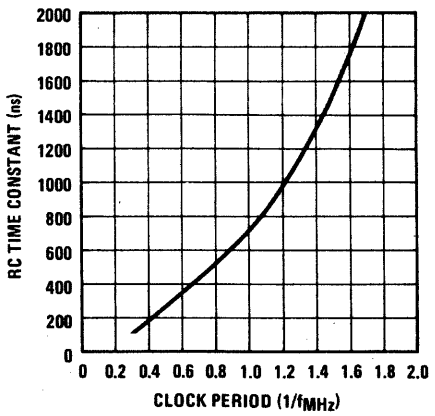
T_C = time period for two cycles of on-chip or external oscillator

f_{osc} = frequency of on-chip oscillator

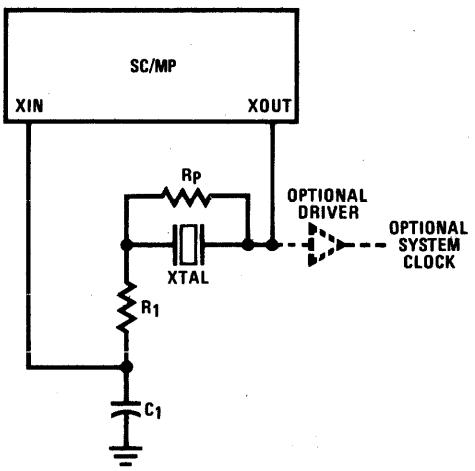


f_{res} = resonant frequency of crystal connected between XIN and XOUT pins

f_{XIN} = frequency of external clock applied to XIN pin



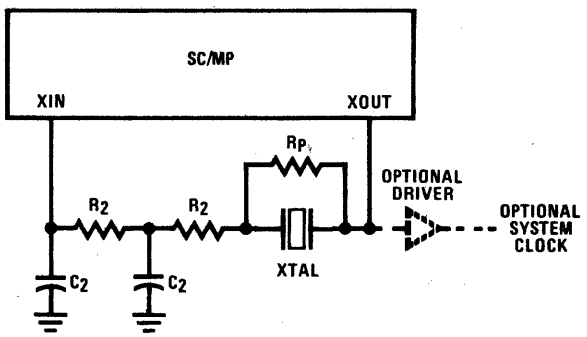
A. External Clock Input



B. Resistor-Capacitor Feedback Network

Typical Oscillator Frequency vs RC Time Constant

C. Crystal with Low-Pass Filter (Above 1MHz)



Suggested values for Crystal with Low-Pass Filter Network.

Crystal	R_P	C_1	R_1
2MHz	100kΩ	56pF	1kΩ
3.58MHz	100kΩ	27pF	1kΩ
4MHz	100kΩ	27pF	1kΩ

XTAL is parallel resonant with maximum series resonance equal to 1kΩ.

D. Crystal with Low-Pass Filter (1MHz or Below)

INSTRUCTION FORMAT

The SC/MP instruction repertoire includes both single-byte and double-byte instructions. A single-byte instruction consists of an 8-bit operation code that specifies an operation that SC/MP can execute without further reference to memory. A double-byte instruction consists of an 8-bit operation code and an 8-bit data or displacement field. When the second byte represents a data field, the data are processed by SC/MP during execution of the instruction, thereby eliminating the need for further memory references. When the second byte represents a displacement value, it is used to calculate a memory address that will be accessed (written into or read from) during execution of the instruction (refer to Addressing).

DATA STORAGE

As shown in figure 1, SC/MP provides ten internal registers, seven of which are accessible to the programmer. The purpose and function of these registers are described below.

Program Counter – The program counter is a 16-bit register that contains the address of the instruction being executed. The contents of this register are automatically incremented by one just before each instruction is fetched from memory to enable sequential execution of the stored instructions. Under program control, the contents of this register also may be modified or exchanged with the contents of a pointer register to effect subroutine calls and program branches.

NOTE:

The 16-bit address output of the program counter consists of a 4-bit high-order address and a 12-bit low-order address. When the program counter is incremented at the start of each instruction fetch input/output cycle, only the 12 low-order bits are affected; no carry is provided to the 4 high-order bits. For systems employing memories of 4k or less, the high-order bits can be ignored as they are set to 0000_{16} following initialization. For systems employing larger memories, the contents of a pointer register can be modified to select the desired 4k block of memory.

Pointer Registers – The pointer registers are 16-bit general-purpose registers that normally are loaded under program control with reference addresses that serve as page pointers, stack pointers, and subroutine pointers. In applications having minimal memory addressing requirements, these registers may be used alternately as data storage registers.

NOTE:

When interrupt requests are enabled, pointer register 3 is automatically referenced by the internal microprogram for formation of the starting address of the user-generated interrupt service routine. (See figure 9.) In this case, the contents of pointer register 3 must be set to one less than the memory location of the first instruction in the interrupt service routine.

Accumulator – The 8-bit accumulator (AC) is the primary working register of SC/MP. It is used for performing and storing the results of arithmetic and logic operations as well as for data transfers, shifts, rotates, and data exchanges with the program counter, the pointer registers, and the status register.

Extension Register – The extension register is used both for serial input/output data transfers and with the accumulator to effect arithmetic, logic, and data-transfer operations. If the second byte of an indexed or auto-indexed memory-reference instruction (refer to Addressing) equals -128_{10}, the contents of the extension register are used as the displacement value for address formation.

Status Register – The status register provides storage for arithmetic, control, and software status flags. For more-detailed information on the function of this register, refer to Status Register under the description of the Arithmetic and Logic Unit.

Instruction Register – The 8-bit instruction register is not accessible to the programmer. During the fetch phase of each instruction cycle, this register is loaded with the 8-bit instruction operation code retrieved from memory (for a single-byte instruction or the first byte of a double-byte instruction).

Data Input/Output Register – The data input/output register is not accessible to the programmer. It is used for temporary storage of all input/output data received via or transmitted over the 8-bit bidirectional data bus during the data-transfer interval of each input/output cycle (NRDS or NWDS low).

Address Register – The 16-bit address register is not accessible to the programmer. It is used for temporary storage of the 16-bit address transmitted during an input/output cycle.

ARITHMETIC AND LOGIC UNIT

The Arithmetic and Logic Unit (ALU) provides the data-manipulation capability that is an essential feature of any microprocessor. The operations provided by the ALU include OR, XOR, increment, decrement, binary addition, and decimal addition. For decimal addition, the data inputs to the ALU are treated as two 4-bit BCD digits, thereby eliminating the program-storage and execution time required to perform BCD to binary conversion.

BUS TRANSFER LOGIC

The bus transfer logic processes the gating and function control outputs of the instruction-decode logic to provide the shift-right (with link, without link, or with serial input data), rotate (with or without link), and bus-exchange functions necessary for data movement between the SC/MP internal read and write busses. A general summary of the data-manipulation capabilities available to the programmer follows.

1. Either the low-order or the high-order byte of any pointer register can be exchanged with the contents of the 8-bit accumulator. Thus, data exchanges between the pointer registers can be effected one byte at a time via the accumulator.

2. The contents of the program counter can be directly exchanged with the contents of any pointer register.

3. The contents of the extension register can be loaded into the accumulator or can be exchanged with the contents of the accumulator. When the accumulator is loaded from the extension register, the original contents of the accumulator are lost.

4. The contents of the status register can be copied into the accumulator to enable status modification or conditional-branch testing. When the status register is copied into the accumulator, the contents of the status register are not altered but the original contents of the accumulator are lost.

5. The contents of the accumulator can be copied into the status register to change the outputs of the status register, except for status bits 4 and 5 (Sense A and B inputs to SC/MP). Since these are read-only bits, they are not affected by data movements internal to SC/MP. Copying the accumulator into the status register does not alter the contents of the accumulator.

NOTE:

The flag 0, 1, and 2 outputs of the status register serve as latched flags; in other words, they are set to the specified state when the contents of the accumulator are copied into the status register, and they remain in the specified state until the contents of the status register are modified again under program control.

STATUS REGISTER

The function of each bit in the status register is described briefly below.

7	6	5	4	3	2	1	0
CY/L	OV	S_B	S_A	IE	F_2	F_1	F_0

User Flag 0 — User-assigned general-purpose status bit for implementation as software status bit or in system control applications. This status bit is available as an external output from SC/MP.

User Flag 1 — Same as User Flag 0.

User Flag 2 — Same as User Flag 0.

Interrupt Enable Flag — Internal status bit that is set and reset under program control. When set, SC/MP recognizes external interrupt requests received via Sense A input. When reset, inhibits SC/MP from recognizing interrupt requests.

Sense A — General-purpose status input for sensing external conditions. When IE flag is reset, this bit can be tested by copying status register to accumulator. When IE flag is set, this bit serves as interrupt request input causing SC/MP to automatically branch to user-generated interrupt-service routine in response to high input.

Sense B — Same as Sense A except that it is not tested for interrupt status.

NOTE:

Sense A and B inputs are read-only bits. Thus, they are not affected when the contents of the accumulator are copied into the status register.

Overflow (OV) — This bit is set if an arithmetic overflow occurs during an add (ADD, ADI, or ADE) or a complement-and-add instruction (CAD, CAI, or CAE). It is not affected by the decimal-add instructions (DAD, DAI, or DAE).

Carry/Link (CY/L) — This bit is set if a carry from the most significant bit occurs during an add, complement-and-add, or decimal-add instruction. Thus, it serves as a carry input to the next add instruction. In addition, it is included in the Shift Right with Link (SRL) and Rotate Right with Link (RRL) instructions.

CONTROL

The operation of the SC/MP microprocessor consists of repeatedly accessing or fetching instructions from the program stored in external memory and executing the operations specified by the instructions. These two steps are carried out under the control of an internal microprogram. (SC/MP is not user-microprogrammable.) The microprogram is similar to a state table specifying the series of states of system control signals necessary to carry out each instruction. Microprogram storage is provided in the instruction decode and control logic, and microprogram routines are implemented to fetch and execute instructions. The fetch routine first increments the program counter, and then causes the instruction address to be transferred from the program counter to the system busses via the output address register. The microprogram next initiates an input data transfer. When the instruction operation code is subsequently placed on the 8-bit data bus (single-byte instruction or first byte of double-byte instruction), the operation code is loaded into the instruction register. The operation code is then partially decoded to determine whether the instruction contains a second byte. If it does, a second input data transfer is effected to load the next byte in the data input/output register.

After the complete instruction is stored in the instruction and/or data input/output register(s), the instruction decoder transforms the instruction operation code into the address of the appropriate instruction-execution routine contained in the internal microprogram. The microprogram then branches to the specified internal address to initiate execution of the instruction. The resulting execution routine comprises one or more microinstructions that implement the required functions. For example, the first microcycle of an Extension Register Add Instruction (ADE) causes the contents of the extension register to be gated onto the read bus, transferred to the write bus via the bus control logic, and then written into the data input/output register. The next microcycle causes the contents of the accumulator to be gated onto the read bus, the contents of the read bus to be added to the contents of the data input/output register via the ALU, and the resultant output of the ALU to be written into the accumulator via the write bus. The final step of the execution routine is a jump back to the fetch routine to access the next instruction.

INITIALIZATION

Since SC/MP may power up in a random condition, the following power-up and initialization procedure is recommended.

1. Apply power (GND and V_{CC}) and set NRST low.

NOTE:

Allow ample time (typically, 250 ms) for the oscillator and the internal clocks to stabilize. In systems where NRST is set low after turning on power, NRST must remain low for a minimum of $4T_C$. While NRST is low, any in-process operations are aborted automatically. When NRST is low, strobes and address and data busses are in the Non-I/O state (high-Z state).

©IC MASTER 1978

2. Set NRST high. If the rise time of this input is too slow, the processor, first, will initialize and execute a few instructions and, then, will reinitialize. If the application is such that multiple initialization is undesireable, NRST should be brought high at a minimum rate of 2 volts per microcycle.

NOTE:

This causes the SC/MP internal control circuit to set the contents of all programmer-accessible registers to zero. Thus, when SC/MP is granted access to the system busses following initialization, the first instruction is fetched *always* from memory location 0001_{16}. The NBREQ output goes low, indicating the start of this input/output cycle; this occurs at a time within $13T_C$ after NRST is set high. Normal execution of the program continues as long as NRST remains high.

parallel data transfers

Parallel data transfers occur during each instruction fetch and during the ensuing read/write cycle associated with execution of the memory-reference instructions. This class of instruction could perhaps more properly be called the "Input/Output Reference Class" in the case of the SC/MP microprocessor, since all data transfers, whether with memory, peripheral devices, or a central processor data bus, occur through the execution of these instructions. This unified bus structure is in contrast with many other microprocessors and minicomputers that have one instruction type (input/output class) for communication with peripheral devices and another instruction type (memory reference class) for communication with memories. The advantage of the approach taken by SC/MP is that a wider variety of instructions (the entire memory-reference class) is available for communications with peripherals. Thus, the LD and ST (Load and Store) instructions can be used for basic transfers, the ILD and DLD (increment/decrement and load) instructions can be used for indexing peripheral registers, and the remaining memory reference instructions can be used, as required, for "one-step" retrieval and processing of peripheral input data.

BUS UTILIZATION

The bus utilization of SC/MP is shown in table 2.

NBREQ, NENIN, and NENOUT are active and bus access is controlled as shown in figure 4. If NENIN is returned high during an input/output cycle, the input/output cycle is repeated when NENIN is again returned low.

During an ILD or DLD instruction, SC/MP does not relinquish the bus between the loading of the data and the storing of the modified data. If NENIN is brought high after the data have been loaded, the load portion of the cycle is not repeated when NENIN is returned low.

BUS ACCESS

Before SC/MP can initiate parallel data transfers with memory or peripheral devices, it must have access to the system address and data busses. Three of the SC/MP input/output signals are associated with bus control: NBREQ, NENIN, and NENOUT. For simple stand-alone applications, the NENOUT signal can be ignored and the NENIN signal can be tied to GND to allow the SC/MP microprocessor to have continual access to the system busses. The NBREQ input/output line then goes low during each input/output cycle as shown in figures 5 and 6 to indicate when SC/MP is actually using the system busses.

NOTE:

The NBREQ input/output line must be tied to V_{CC} via an external load resistor to allow normal operation of the SC/MP microprocessor.

For DMA and multiprocessor applications, the NBREQ, NENIN, and NENOUT signals can be interconnected in various configurations to allow bus access to be granted to requesting devices according to user-specified priorities. Figure 4 illustrates the general sequence in which these signals are processed by SC/MP to gain access to the system busses and to indicate when the busses are actually being used.

INPUT/OUTPUT CYCLE

Once SC/MP has control of the system busses, the actual input/output cycle begins. As shown in figures 5 and 6, the functions of memory addressing, data reading, and data writing are implemented, respectively, by the address strobe (NADS), the read strobe (NRDS), and the write strobe (NWDS). Note that the NBREQ signal is reset high at the end of the input/output cycle to indicate that the system busses are now free for use by the highest-priority requesting device.

The first operation that SC/MP performs for each input/output cycle is to load the 12 least significant address bits onto the 12-bit address bus, and the 4 most significant address bits along with 4 status bits onto the 8-bit data bus. At the same time, SC/MP sets the NADS output low to indicate that the address and the status information are valid. The low-order address on the 12-bit bus is then held valid for the duration of the input/output cycle; the high-order address and the status information on the 8-bit bus remain valid only while NADS is low. While valid, the status bits have the following significance:

RFLG – When high, indicates that input/output cycle is read cycle; when low, indicates that input/output cycle is write cycle.

IFLG – Set high to indicate that instruction operation code (single-byte instruction or first byte of double-byte instruction) will be output from memory following NADS.

DFLG – Set high only when second byte of Delay Instruction is to be read from memory following NADS. Execution of the Delay Instruction then starts at trailing edge of NRDS. Upon completion, SC/MP provides NADS output to initiate next input/output cycle if bus access is granted. Time in microcycles from leading edge of delay flag to leading edge of subsequent NADS output is computed from the following formula:

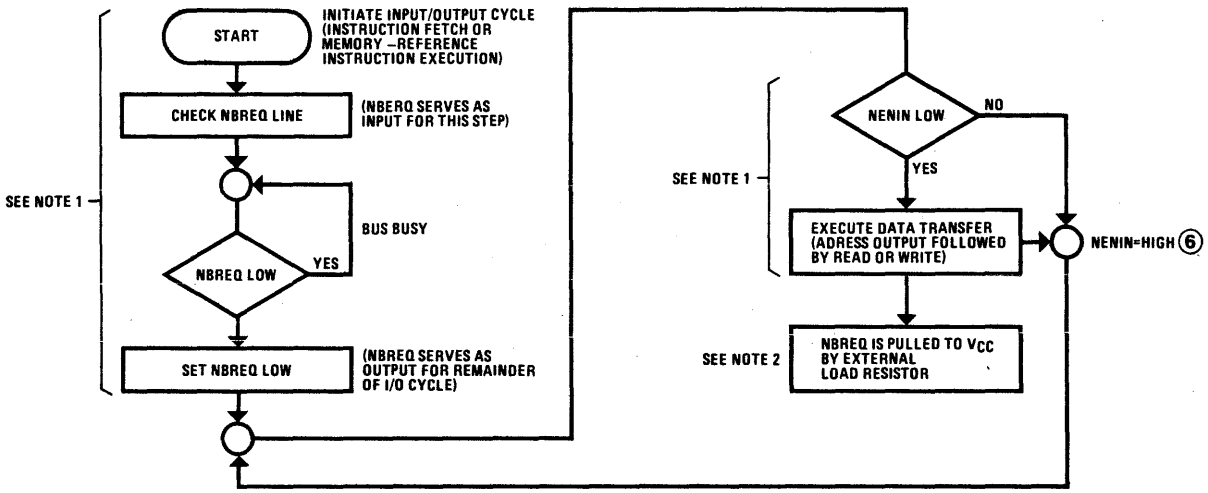
$$\text{Delay} = [9 + 2(\text{AC}) + 2\ \text{disp} + 2^9\ \text{disp}]\ \text{microcycles}$$

where

(AC) = unsigned contents of accumulator

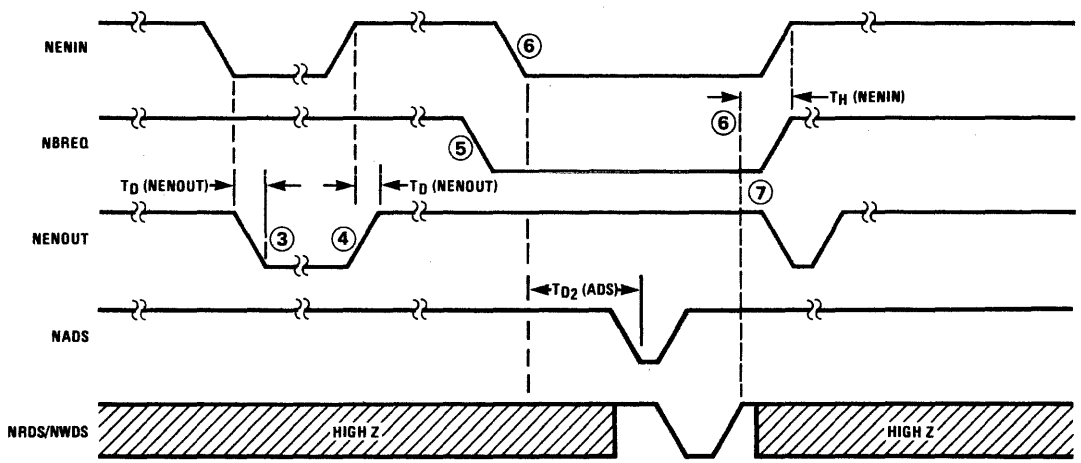
disp = unsigned displacement value contained in second byte of Delay Instruction

The time derived from the above formula does not include the four microcycles required to fetch the first byte of the Delay Instruction. Thus, when the Delay



©IC MASTER 1978

Instruction is used for software timing, total instruction execution time equals [13 + 2(AC) + 2 disp + 2^9 disp] microcycles.



NOTE:

When Halt Instruction is executed, instruction decode and control logic inhibits incrementing of program counter for one input/output cycle. Thus, Halt Instruction is read from memory a second time to enable generation of HFLG output, but no further processing of Halt Instruction occurs. In effect, this procedure ensures HFLG is output in advance of the next instruction to be fetched from memory.

HFLG – Set high only during addressing interval of read cycle that follows Halt Instruction. HFLG may be used to cause user-provided external logic to set the CONT input low, and thereby to effect a programmed halt. Since HFLG read cycle precedes the next instruction

A. NBREQ and NENIN Processing Sequence

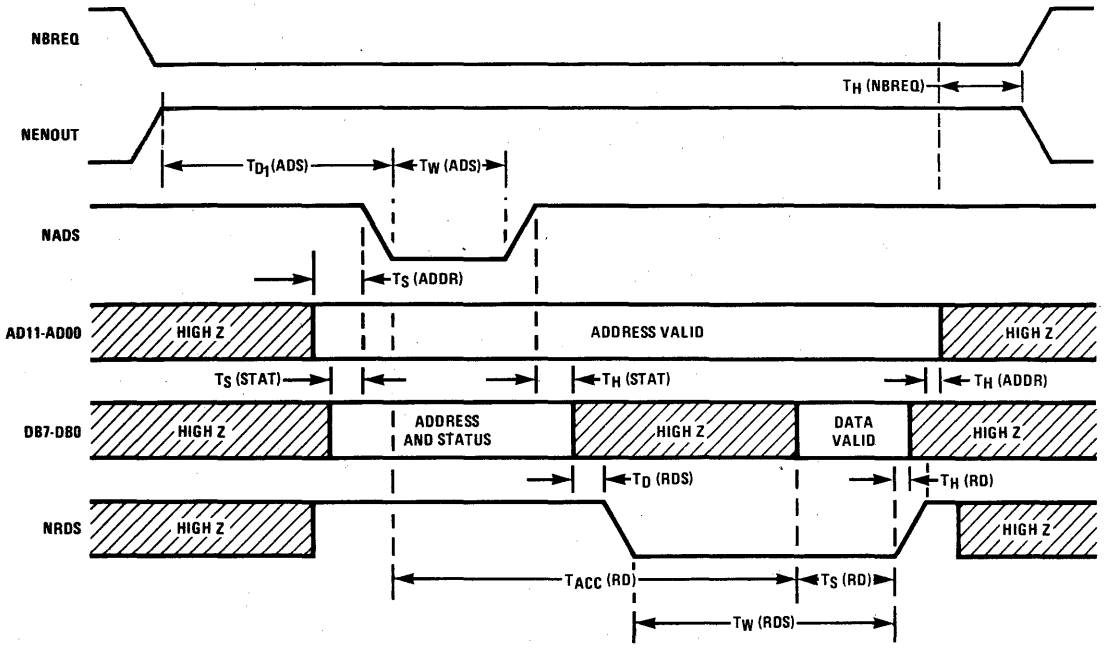
B. NBREQ, NENIN, and NENOUT Timing

Note 1: NENOUT is always high while SC/MP is actually using bus; that is, NENIN input and NBREQ output are low.

Note 2: When SC/MP is not using bus (NBREQ output or NENIN input high), NENOUT is held in same state as NENIN input.

Note 3: NENOUT goes low to indicate that SC/MP was granted access to bus (NENIN low) but is not using bus.

Note 4: NENOUT goes high in response to high NENIN input.



Note 5: SC/MP generates bus request; bus access not granted because NENIN high.

Note 6: NENIN goes low. Bus access now granted and input/output cycle actually initiated. If NENIN is set high while SC/MP has access to the bus, the address and data ports will go to the high-impedance (Tri-State®) state, but NBREQ will remain low. When NENIN is subsequently set low, the input/output cycle will begin again.

Note 7: Input/output cycle completed. NENOUT goes low to indicate that SC/MP granted access to bus but not using bus. If NENIN had been set high before completion of input/output cycle, NENOUT would have remained high.

FIGURE 4. Bus Access Control

©IC MASTER 1978

Note: Timing is valid when NENIN is low before NBREQ is set low by SC/MP; see figure 4 for NADS timing when NENIN is set low after NBREQ.

FIGURE 5. SC/MP Data Input Timing

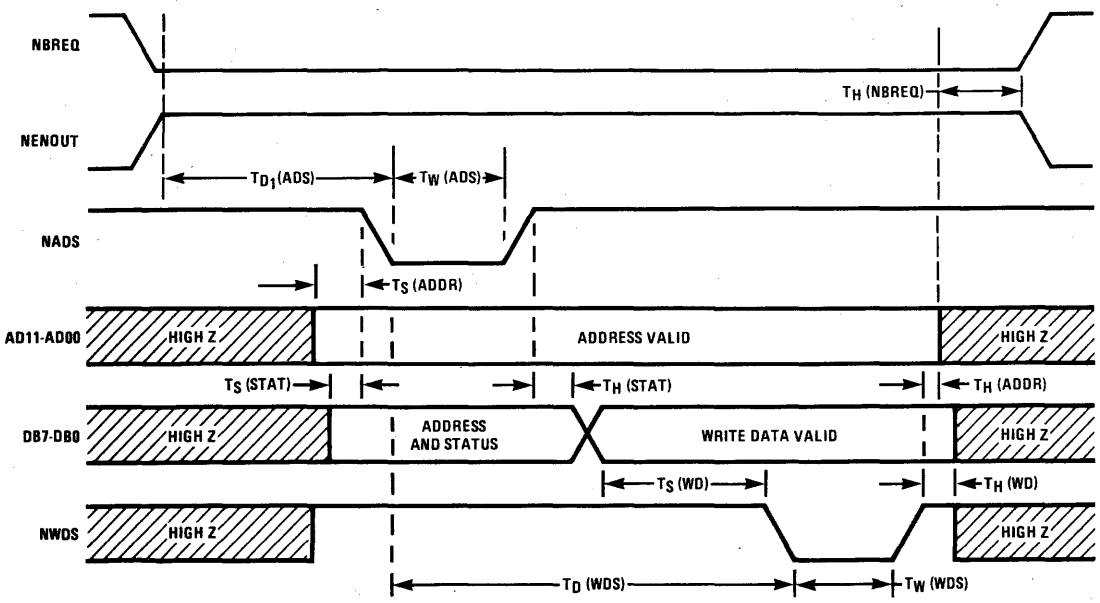


FIGURE 6. Data Output Timing

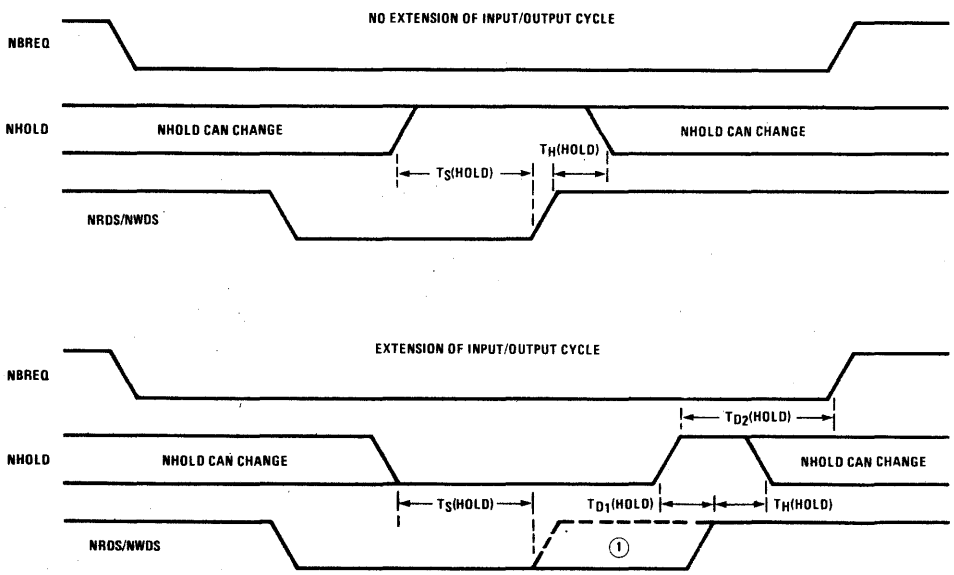
©IC MASTER 1978

fetch, termination of programmed halt enables fetch of first instruction that follows Halt Instruction.

After resetting the NADS output, SC/MP generates an NRDS or NWDS strobe, respectively, to initiate a data-input (read) or data-output (write) operation. For a read operation, input data are strobed into SC/MP from the 8-bit bus on the trailing edge of the NRDS strobe. For a write operation, SC/MP places valid output data on the 8-bit bus on the leading edge of the NWDS strobe. After resetting the NRDS or NWDS strobe to complete the data transfer, SC/MP then resets the NBREQ signal to indicate that the system busses are free for use by another controller.

INPUT/OUTPUT CYCLE EXTENSION



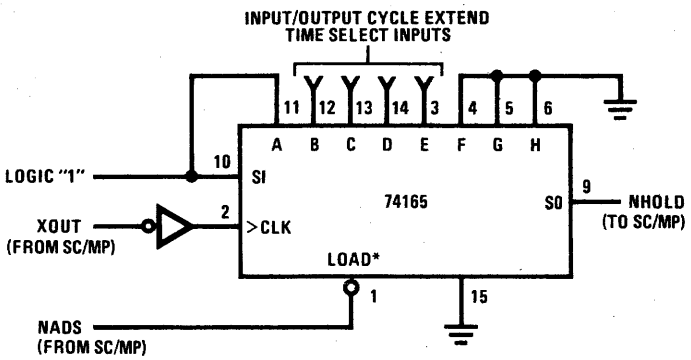
As shown in figure 7, the NHOLD signal may be set low prior to the trailing edge of the NRDS or NWDS strobe to cause SC/MP to lengthen the input/output cycle by holding the strobe active until after the NHOLD signal is returned high. Since there is no restriction on the maximum duration of the NHOLD signal, it can be used in a variety of applications ranging from accommodation of memories/peripherals with long access times to single-cycle control of the operating program for software debug purposes.

Figure 8 illustrates a typical circuit that may be used to generate an NHOLD signal of repeatable duration. The circuit shown employs a DM74165 8-Bit Parallel In/Serial Out Shift Register to allow selection of an input/output cycle extend time that ranges from $T_C/2$ to $2T_C$ in increments of $T_C/2$. Functional operation of the circuit is controlled by the NADS strobe and XOUT signals. Each time that the NADS strobe goes low, the data present at the A through H terminals are loaded into the shift register in parallel. When the NADS strobe subsequently returns high, the data are then shifted out serially on the positive-to-negative transitions of XOUT. Thus, the NHOLD output of the circuit is set low on the leading edge of each NADS strobe and, as shown in the chart that accompanies the circuit diagram, it remains low for a time period ranging from three clock cycles minimum (B, C, D, and E inputs = Logic "1") to seven clock cycles maximum (B, C, D, and E inputs = Logic "0").

It is important to note that instruction execution time is increased whenever an input/output cycle is extended via the NHOLD signal. For purposes of computing the increase in instruction execution time, it is necessary to distinguish between the terms *Input/Output Cycle Delay Period* and *Input/Output Cycle Extend Time*. The term *Input/Output Cycle Delay Period* refers to the time that the NRDS/NWDS strobe is actually "stretched" to provide the required memory or peripheral access time. The term *Input/Output Cycle Extend Time* refers to the additional number of microcycles required by the internal SC/MP microprogram to complete the extended input/output cycle; that is:

Input/Output Cycle Delay Period	Input/Output Cycle Extend Time
$T_C/2$ through $2T_C$ ($> 0 \leqslant 1$ μcycle)	1 μcycle
$5T_C/2$ through $4T_C$ ($> 1 \leqslant 2$ μcycles)	2 μcycles
$9T_C/2$ through $6T_C$ ($> 2 \leqslant 3$ μcycles)	3 μcycles
etc.	etc.

The total increase in instruction execution time, therefore, is equal to the *Input/Output Cycle Extend Time* multiplied by the total number of input/output cycles associated with the instruction. For example, a DLD Instruction is normally executed in 22 microcycles. Since this instruction employs three read input/output cycles and one write input/output cycle, an *Input/Output Cycle Extend Time* of one microcycle would increase total DLD Instruction execution time to 26 microcycles.



Note 1: In order to extend the input/output cycle, NHOLD must remain low until the point where NRDS/NWDS would have made a low-to-high transition with NHOLD inactive. Dashed line indicates the trailing edge of NRDS/NWDS when NHOLD is not active.

Data Inputs B C D E	NHOLD Duration (in clock cycles)	Input/Output Cycle		Required Memory Access Time [T_{ACC} (RD)]
		Delay Period	Extend Time in Microcycles	
1 1 1 1	3	0	0	$2T_C - 200$
1 1 1 0	4	$T_C/2$	1	$(5T_C/2) - 200$
1 1 0 0	5	T_C	1	$3T_C - 200$
1 0 0 0	6	$3T_C/2$	1	$(7T_C/2) - 200$
0 0 0 0	7	$2T_C$	1	$4T_C - 200$

FIGURE 8. Typical NHOLD Control Circuit

serial data transfers

Serial input/output data transfers can be used efficiently with very slow input/output peripherals such as X-Y plotters, teletypewriters, slow-speed printers, and so forth. Such transfers can be effected in any of the following manners:

1. By assigning serial input/output functions to the extension register via the SIO (Serial Input/Output) Instruction. When this instruction is executed, the contents of the extension register are shifted right one bit. At the same time, data present on the SIN line are shifted into bit position 7 of the extension register and the original contents of bit position 0 are shifted into a flip-flop to provide a latched output of the SOUT line. The SOUT data are then held latched until the next SIO instruction is executed.

2. By using one of the status flags as an output data bit and one of the sense lines as an input data bit.

3. By implementing external logic such that only one line of the 8-bit data input/output bus is used.

For synchronous systems, serial data input/output timing may be provided by program loops that employ the delay instruction, or by using one or more of the transfer instructions (see table 2) to test the output of an external timing circuit. For asynchronous systems, one of the sense inputs can be used for testing bit-received/ready status and a pulsed flag output can be provided, under program control, for peripheral indexing each time that a data bit is actually shifted in or out.

Systems that have several input/output devices must be multiplexed; device selection can then be accomplished using the status flag outputs of SC/MP, or by using parallel input/output commands to load an external latch. Systems that do not require serial input/output capability can employ the SIN and SOUT lines as a sense input and flag output, respectively.

interrupts

When the internal interrupt enable (IE) flag is set under program control, the Sense A line is enabled to serve as an interrupt request input; when the IE flag is reset, SC/MP is inhibited from detecting interrupts. Thus, while the IE flag is set, the Sense A input is tested prior to the fetch phase of each instruction as shown in figure 9. Upon detection of an interrupt request (Sense A high), the following events occur automatically.

1. The status register IE flag is reset to prevent SC/MP from responding to any further interrupt requests. Interrupt request capability can then be reenabled during or at the end of the ensuing user-generated interrupt service routine via the IEN (Enable Interrupt) Instruction or by copying the accumulator into the status register.

2. The contents of the program counter are exchanged with the contents of the pointer register 3.

3. The contents of the program counter are incremented by one to address the first instruction of the user-generated interrupt service routine.

The interrupt system must be armed before interrupts are enabled. This is accomplished as follows:

1. First, the Interrupt Enable Bit in the Status Register is set true by executing either an Enable Interrupt Instruction (IEN) or a Copy Accumulator to Status Register Instruction (CAS).

©IC MASTER 1978

2. Second, one additional instruction is fetched and executed.

A return from interrupt is accomplished by executing two instructions: Enable Interrupt (IEN) immediately followed by Exchange Pointer 3 with Program Counter (XPPC 3).

microprocessor halt

The CONT input to SC/MP is provided to enable suspension of operation without loss of internal status. Processing of the CONT input is shown in figure 9. Since this is an asynchronous input, it can be controlled by external timing logic, or as stated previously, the HALT flag output that appears on the 8-bit data bus (during the read cycle that follows execution of a Halt Instruction) can be used with an external circuit to effect a programmed halt condition. Note that when an interrupt request is detected while the CONT input is low, the first instruction of the user-generated interrupt service routine is automatically executed. Thus, the first instruction of the interrupt service routine can be used to reset the external CONT input logic and, thereby, to terminate the microprocessor halt condition if so desired.

After execution of an instruction, the CONT input must be high for a minimum time of $2T_C$ (1 microcycle) in order to fetch and execute the next instruction.

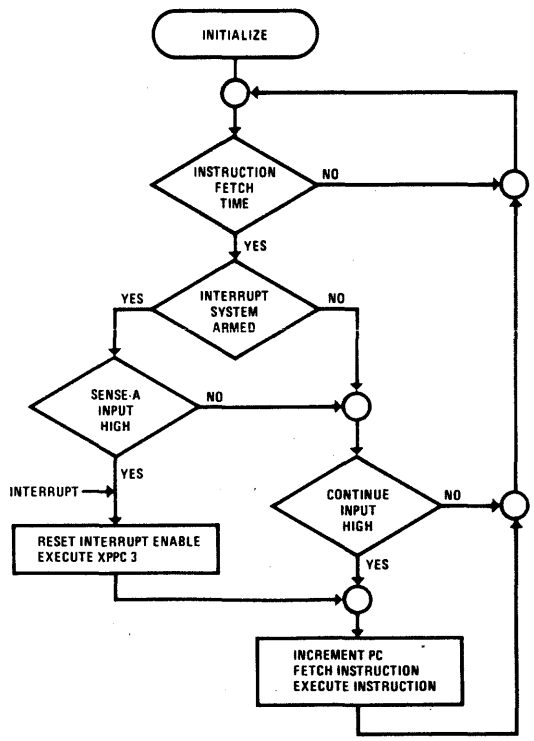

FIGURE 9.

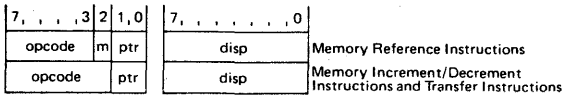

Microprocessor Halt and Interrupt Request Input Processing

instruction set

The SC/MP instruction set provides the general-purpose user of microprocessors a powerful programming capability along with above-average flexibility and speed. The instruction set consists of 46 instructions, which comprise eight general categories. A listing of the complete instruction set is provided in table 2; typical instruction execution times are given in table 3, and notations and symbols used as shorthand expressions of instruction capability are defined in table 4.

ADDRESSING

During execution, instructions and data defined in a program are stored into and loaded from specific memory locations, the accumulator, or selected registers. Because SC/MP, memory (read/write and read-only), and peripherals are on a common data bus, any instruction used to address memory may be used to address the peripherals. The formats of the instruction groups that reference memory are shown below.

Memory-reference instructions use the PC-relative, indexed, or auto-indexed methods of addressing memory. The memory-increment/decrement instructions and the transfer instructions use the PC-relative or indexed methods of addressing.

The various methods of addressing memory and peripherals are shown below.

Immediate addressing is an addressing format specific to the immediate instruction group.

Type of Addressing	Operand Formats		
	m	ptr	disp
PC-relative	0	0	-128 to +127
Indexed	0	1, 2, or 3	-128 to +127
Immediate	1	0	-128 to +127
Auto-indexed	1	1, 2, or 3	-128 to +127

For PC-relative, indexed, and auto-indexed memory-reference instructions, another feature of the addressing architecture is that the contents of the extension register are substituted for the displacement if the instruction displacement equals -128 (-X'80).

NOTE:

All arithmetic operations associated with address formation affect only the 12 low-order address bits; no carry is provided to the 4 high-order bits. For systems employing memories of 4k or less, the high-order bits can be ignored as they are set to 0000 following initialization. For systems employing larger memories, the high-order bits must be set to the starting address of the desired 4k block of memory. For example:

0001_2 enables memory locations 1000_{16} - $1FFF_{16}$ to be addressed.

0010_2 enables memory locations 2000_{16} - $2FFF_{16}$ to be addressed and so forth.

PC-Relative Addressing – A PC-relative address is formed by adding the displacement value specified in the operand field of the instruction to the current contents of the program counter. The displacement is an 8-bit twos-

©IC MASTER 1978

complement number, so the range of the PC-relative addressing format is -128_{10} to $+127_{10}$ locations from the current contents of the program counter.

Immediate Addressing – Immediate addressing uses the value in the second byte of a double-byte instruction as the operand for the operation to be performed (see below).

For example, compare a Load (LD) instruction to a Load Immediate (LDI) instruction. The Load instruction uses the contents of the second byte of the instruction in computing the effective address of the data to be loaded. The Load Immediate instruction uses the contents of the second byte as the data to be loaded.

Indexed Addressing – Indexed addressing enables the programmer to address any location in memory through the use of the pointer register and the displacement. When indexed addressing is specified in an instruction, the contents of the designated pointer register are added to the displacement to form the effective address. The contents of the pointer register are not modified by indexed addressing.

Auto-Indexed Addressing – Auto-indexed addressing provides the same capabilities as indexed addressing along with the ability to increment or decrement the designated pointer register by the value of the displacement. If the displacement is less than zero, the pointer register is decremented by the displacement before the contents of the effective address are fetched or stored. If the displacement is equal to or greater than zero, the pointer register is used as the effective address, and the pointer register is incremented by the displacement after the contents of the effective address are fetched or stored.

system implementation

Figures 10 through 12 illustrate typical SC/MP system configurations. In figure 10, SC/MP is shown interconnected to three memory devices to form a stand-alone 4-device system that provides 256 words of read/write memory and 2,048 words for program storage. Figure 11 shows SC/MP interconnected to an external controller for Direct Memory Access (DMA) operation, and figure 12 illustrates a multiprocessor application using SC/MP's built-in logic to control bus access.

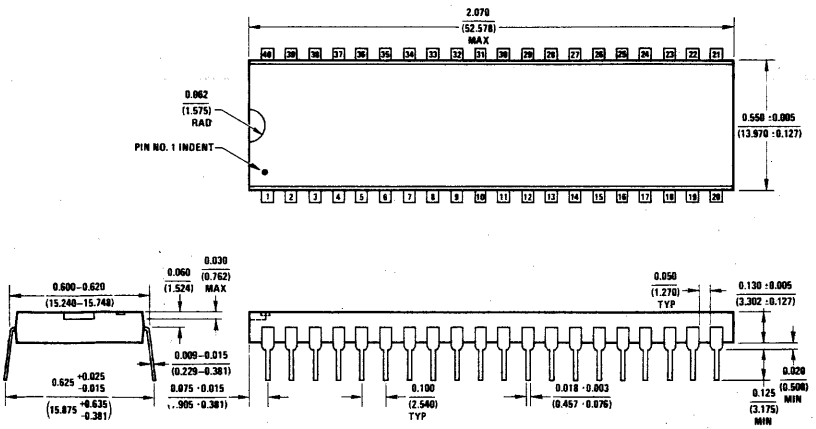
TABLE 5. Symbols and Notations Used to Express Instruction Execution



SYMBOL AND NOTATION	MEANING
AC	8-bit Accumulator.
CY/L	Carry/Link Flag in the Status Register.
data	Signed, 8-bit immediate data field.
disp	Displacement; represents an operand in a nonmemory reference instruction or an address modifier field in a memory reference instruction. It is a signed twos-complement number.
EA	Effective Address as specified by the instruction.
E	Extension Register; provides for temporary storage, variable displacements and separate serial input/output port.
i	Unspecified bit of a register.
IE	Interrupt Enable Flag.
m	Mode bit, used in memory reference instructions. Blank parameter sets m = 0, @ sets m = 1.
OV	Overflow Flag in the Status Register.
PC	Program Counter (Pointer Register 0); during address formation, PC points to the last byte of the instruction being executed.
ptr	Pointer Register (ptr = 0 through 3). The register specified in byte 1 of the instruction.
$ptr_{n:m}$	Pointer register bits; n:m = 7 through 0 or 15 through 8.
SIN	Serial Input pin.
SOUT	Serial Output pin.
SR	8-bit Status Register.
( )	Means "contents of." For example, (EA) is contents of Effective Address.
[ ]	Means optional field in the assembler instruction format.
~	Ones complement of value to right of ~.
→	Means "replaces."
←	Means "is replaced by."
↔	Means "exchange."
@	When used in the operand field of the instruction, sets the mode bit (m) to 1 for auto-incrementing/auto-decrementing indexing.
10^+	Modulo 10 addition.
∧	AND operation.
∨	Inclusive-OR operation.
⊻	Exclusive-OR operation.
⩾	Greater than or equal to.
=	Equals.
≠	Does not equal.

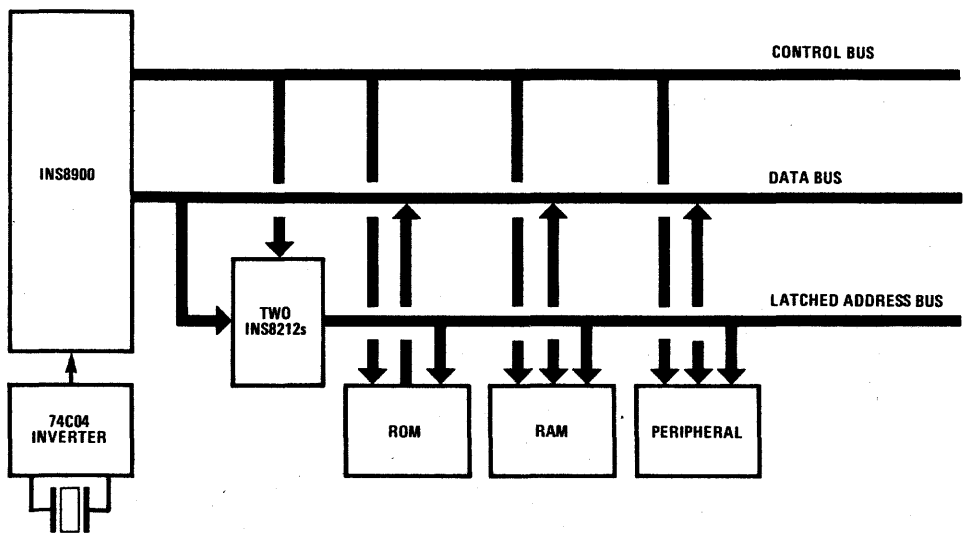
Preliminary

INS8900 Single-Chip 16-Bit N-Channel Microprocessor



General Description

The INS8900 is a single-chip 16-bit microprocessor housed in a standard hermetically sealed 40-pin ceramic dual-in-line package. The INS8900 is fabricated using N-channel silicon gate MOS technology. The INS8900 is intended for use in applications where the convenience and efficiency of 16-bit word length is desired while maintaining the low cost inherent in single-chip fixed instruction microprocessors. The INS8900 is a true 16-bit central processor unit: it makes use of 16-bit instruction words and 16-bit data words, and features a powerful, efficient, and flexible set of 46 instructions. All instructions use a single-word 16-bit format, thus reducing memory accesses and program storage requirements. A unique feature of the INS8900 is the ability to operate on both 8-bit and 16-bit data words: this extends the inherent efficiency and power of a 16-bit processor to 8-bit applications.

Features

- 46 Instruction Types
- All Instructions Single Word
- Multiple Addressing Modes
  - Program-Counter Relative
  - Base Page
  - Indexed
  - Direct and Indirect
- Four General-Purpose Accumulators
- Byte and Word Processing
- Common Memory and Peripheral Addressing
- Six Hardware-Vectored Priority Interrupts
- 10-Word On-Chip Stack
- Three Control Flag Outputs
- Three Sense Inputs
- Four I/O Control Strobe Signals
- Single-Phase 2 MHz Clock
- Low-Power Schottky Compatible Outputs

Figure 8. Relative Timing for Processor Stall

The architecture of the INS8900 (shown in Figure 9) features a number of resources to minimize system program and read/write storage, increase throughput, and reduce the amount and cost of external support hardware. Principal resources that allow these efficiencies to be achieved include:

Four 16-bit general purpose working registers available to the user reduce the number of memory load and store operations associated with saving temporary and intermediate results in system memory.

An independent 16-bit status and control flag register automatically and continuously preserves system status. The user may operate on its contents as data, allowing masking, testing, and modification of several bit fields simultaneously.

A ten-word (16-bit) last-in, first-out (LIFO) stack inherently decreases response time to interrupts while eliminating both program and read/write system storage overhead associated with storing stack information outside the microprocessor chip.

Stack full/stack empty interrupts are provided to facilitate off-chip stack storage in those applications where additional stack capacity is desirable.

A six-level vectored priority interrupt system internal to the chip provides automatic interrupt identification, eliminating both program storage overhead and the time normally required to poll peripherals in order to identify the interrupting device.

Three sense inputs and four control flag outputs allow the user to respond directly to specific combinations of status present in the microprocessor-based system, thus eliminating costly hardware, program overhead, and throughput associated with implementing these functions over the system data bus.

A comprehensive set of input/output control signals provided by the internal control logic simplifies interfaces to memory and peripherals and allows flexible control of INS8900 operations.

Single-phase 2.0 MHz clock input is easily generated with a minimum of external components.

INS8900 FUNCTIONAL PIN DEFINITIONS

The functions of each of the INS8900 signals are described below. Voltage and timing specifications for the signals are provided in the table of electrical characteristics and the timing diagrams, respectively.

CLKX (Input): External clock input (single-phase).

D00–D15 (Input/Output): Data bus lines. Bidirectional low-power Schottky-compatible lines used for input and output of data and for output of 16-bit addresses on I/O cycles.

NADS (Output): Address Data Strobe. The negative-true NADS signal is sent out at the beginning of every data input/output cycle and indicates that a memory or peripheral address has been output on the data bus lines. The address is stable on the data bus while the NADS signal is active low.

ODS (Output): Output Data Strobe. The ODS signal indicates to external circuits that the data bus contains valid output data.

IDS (Output): Input Data Strobe. The IDS signal indicates to external devices that the INS8900 is performing a data input cycle. The signal should be used by memory or peripheral devices to gate data onto the INS8900 data bus lines.

EXTEND (Input): Extended Data Transfer. The EXTEND signal is used by slower memory or peripheral devices to temporarily increase the time duration of data input/output transfers. The EXTEND signal should be driven high at the beginning of an ODS or IDS signal and held high until output data has been captured or input data is made available to the data bus. The EXTEND signal can also be used to suspend input/output operations by applying the signal after the end of ODS or IDS.

JC13, JC14, JC15 (Input): Jump Conditions 13, 14, and 15. JC13, -14, and -15 are user-specified inputs that can be tested using the Branch-On-Condition (BOC) Instruction. If the jump condition input specified in the BOC Instruction is high, a program branch is effected. The JC13–JC15 signals are useful for testing status of external devices and receiving serial data.

F11, F12, F13, F14 (Output): General-purpose control flag outputs from the INS8900 Status and Control Flag Register. Individual flags may be set by the Set Flag Instruction (SFLG) and pulsed or reset by the Pulse Flag Instruction (PFLG). The F11–F14 signals may be used for direct control of system functions or serial data output.

NIR2, NIR3, NIR4, NIR5 (Input): Interrupt Requests 2, 3, 4, and 5. When these negative-true input signals are low for 1 clock period, minimum, the associated internal Interrupt Request Latch is set if the corresponding interrupt enable has been set by the user's program. The interrupt will be serviced after completion of the current instruction if the Master Interrupt Enable is set. Interrupt Requests are prioritized, with NIR5 having lowest priority.

NHALT (Input/Output): Halt. When the negative-true NHALT signal is driven low by external logic, it effects a microprocessor stall or Level-0 Interrupt, depending on timing of the CONTIN signal. When not controlled by external logic, NHALT is driven low by the INS8900 for 7/8 of a duty cycle while a programmed halt condition exists. Programmed halt is initiated by the Halt Instruction and terminated by pulsing the CONTIN line via external logic.

CONTIN (Input/Output): Continue. The CONTIN signal is used in the input mode to terminate a programmed halt, or to exercise microprocessor stall and Level-0 Interrupt, or as a jump-condition input that can be tested using a BOC instruction. In the output mode, CONTIN transmits an interrupt acknowledge pulse to acknowledge CPU response to an active interrupt input.

BPS (Input): Base Page Select. The BPS signal enables one of two base-page addressing schemes to be selected. When BPS is low, the first 256_{10} words of memory constitute base page (page zero). When BPS is high, the first 128_{10} memory words and the last 128_{10} memory words constitute base page.

NINIT (Input): Initialize. Initialize is applied after power supplies and clock are stable. While the negative-true NINIT signal is low, the INS8900 operation is suspended, and the IDS/ODS signals are set to the inactive state. After NINIT completes a low-to-high transition, the program counter is set to zero, the internal stack pointer is cleared, and all flags and interrupt enables are set low except Level-0 Interrupt Enable, which is set high. All other registers contain arbitrary values.

POWER SUPPLIES

V_{SS}: Ground.

V_{DD}: +12 volts.

V_{CC}: +5 volts.

V_{BB}: –8 volts.

INTERRUPT SYSTEM

The INS8900 microprocessor provides a six-level, vectored, priority interrupt structure. This allows automatic identification of an interrupting device's level and allows all devices on an interrupt level to be enabled or disabled as a group, independent of other interrupt levels. An individual interrupt enable is provided in the status register for each level, as shown in figure 11, and a master interrupt enable (IEN) is provided for all 5 lower priority levels as a group. Negative true interrupt request inputs are provided to allow several interrupts to be wire ORed on each input. When an interrupt request occurs, it will set the interrupt request latch if the corresponding interrupt enable is true. The latch will be set by any pulse exceeding one clock period in duration, which is useful for capturing narrow timing or control pulses. If the master interrupt enable (IEN) is true, then an interrupt will be generated. During the interrupt sequence an address is provided by the output of the priority encoder and is used to access the pointer for the highest-priority interrupt request (IR0 is highest priority, IR5 is lowest priority). The pointers are stored in locations 2-7 (see table 1) for interrupt requests 1-5 and 0, respectively. The pointer specifies the starting address of the interrupt service routine for that particular interrupt level. Before executing the interrupt service routine, the program counter is pushed on the stack and IEN is set false. The interrupt service routine may set IEN true after turning off the interrupt enable for the level currently being serviced (or resetting the interrupt request). [The interrupt enables may be set and reset using the SFLG and PFLG instructions.]

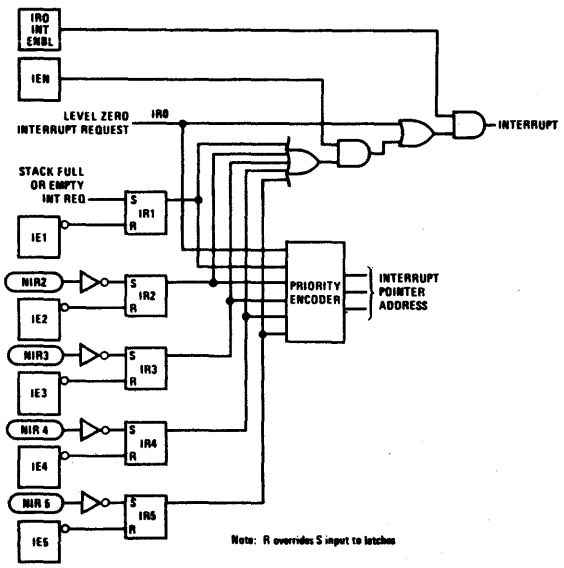

Figure 11. Interrupt System

4	Int 3 Pointer
3	Int 2 Pointer
2	Int 1 Pointer
1	Not Assigned
Loc 0	Initialization Inst

The non-maskable level zero interrupt (IR0) is an exception to this interrupt procedure. It has a program counter storage location pointer (The program counter is not stored on the stack for this particular interrupt in order to preserve the processor state.) which is followed by the level zero interrupt service routine. The IR0 interrupt enable is cleared when a level zero interrupt occurs (IEN is unaffected) and may be set true by setting (non-existent) status flag 15. This allows execution of one more instruction (typically JMP@) to return from the IR0 interrupt routine before another interrupt will be acknowledged. This interrupt level is typically used by a control panel, which then can always interrupt the application program and does not affect system status.

Level zero interrupts are generated by exercising the NHALT and CONTIN lines as shown by the relative timing in figure 7. Note that the CONTIN Signal can be used as an interrupt acknowledge to indicate that the interrupt is being processed by the INS8900.

A processor stall may be implemented by driving the NHALT line low. Microprocessor operation is then suspended upon completion of the instruction presently under execution. The suspension may last indefinitely without loss of CPU status and may be terminated by use of the CONTIN Signal as shown by the relative timing in figure 8.

©IC MASTER 1978

DRIVERS AND RECEIVERS

Equivalent circuits for INS8900 drivers and receivers are shown in figure 12. All inputs have static charge protection circuits consisting of an RC filter and a voltage clamp. These devices should still be handled with care, as the protection circuits can be destroyed by excessive static charge. Pullup transistors on the jump condition inputs are turned on during one of the eight internal clock phases.

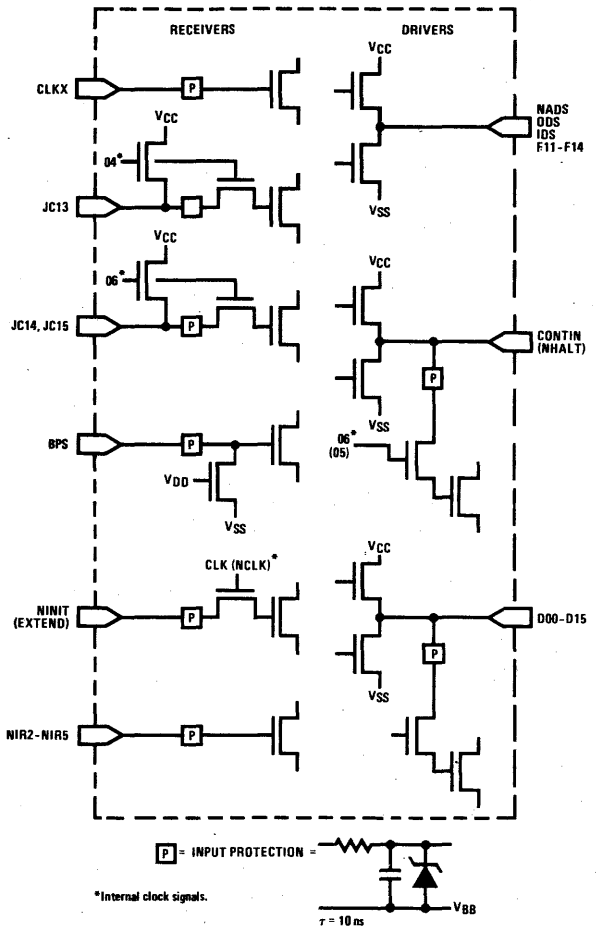

Figure 12. INS8900 Driver and Receiver Equivalent Circuits

EXTERNAL CLOCK TIMING

The INS8900 requires a single-phase clock as shown in figure 1. Refer to the electrical characteristics table for timing specifications.

INITIALIZATION

The INS8900 control circuitry may be initialized at any time by use of the NINIT input signal. The effects of the NINIT signal are described under "INS8900 Interface Signal Descriptions." The NINIT signal should always be used to initialize the processor after applying power. The minimum pulse width for NINIT is 8 clock periods (see figure 2). The INS8900 data strobes (NADS, ODS, IDS) are inactive for 16 to 24 clock periods after the trailing edge of the NINIT signal. After the 16 to 24 clock periods, the first NADS signal occurs and the first instruction is accessed from memory location zero.

Note: If the NINIT signal is held low while clock and/or power are first being applied, the NADS and NHALT outputs may have an undefined state for 8 clock periods after the trailing edge of NINIT.

DATA INPUT/OUTPUT OPERATIONS

All data transfers between the INS8900 and external memories or peripheral devices take place over the 16 data lines. These transfers are synchronized by the NADS, IDS, ODS, and EXTEND signals. Timing for address data output is shown in figure 3. Where signal timing is referenced to CLKX, the reference is to valid logic "1" or logic "0" clock levels. Cross-hatched areas indicate uncertainty of output transitions or "don't care" (optional) states for data inputs. Address data becomes valid one clock phase prior to the Address Data Strobe (NADS) and remains valid for one clock phase afterwards. Typically, NADS will be used to strobe the address data into a latch, either internal or external to the memory chips, or to clock decoded peripheral addresses into a flip-flop.

The INS8900 address output drivers assume a high-impedance state during the data input interval as shown in figure 3. The IDS signal may be used to disable output buffers and enable TRI-STATE® input buffers. Increased power supply current may occur during the transition period of the TRI-STATE enable signal, when several devices may be simultaneously enabled. Therefore, good power, ground layout, and bypass filtering practices should be observed. The data lines must be driven to valid input data logic levels by the end of IDS as specified by t_{DS}. TTL devices should actively drive the input to the right logic level. LS devices, for example, will drive the input to 2.7 V for a logic "1" level. Typically, this data input timing will allow operation of the microprocessor in a system at maximum speed if the access time of the system memory is less than 2 clock periods. For memories with longer access times, the clock frequency may be reduced or the I/O cycle extend feature may be used, as described below.

Data output timing is shown in figure 4. Output data becomes valid at the leading edge of ODS and remains valid for one clock period following the trailing edge. The Output Data Strobe is typically used as a read-write signal for memory and an output data latch strobe for peripheral interfaces.

For systems utilizing memories with access times greater than 2 clock periods it may be desirable to use the EXTEND input to lengthen the I/O cycle by multiples of the clock period. Timing for this is shown in figure 5. In the case of either input or output operations, the extend should be brought true prior to the end of clock phase 6. The timing shown in figure 5 will provide the minimum extend of one clock period. Holding EXTEND true for n additional clock periods will cause an extension of n+1 clock periods.

©IC MASTER 1978

In DMA or multiprocessor systems it may be desirable to prevent I/O operations by the INS8900 when the bus is in use by another device. This may be done immediately following an IDS or ODS signal (a data I/O operation) as shown in figure 6 or at any clock phase 6 regardless of whether a data I/O operation is in progress (as shown in figure 5).

INSTRUCTION SUMMARY

The instruction set is divided into eight instruction classes as listed in table 3. The branch instructions provide the means to transfer control anywhere in the 16-bit addressing space. Conditional branches are effected using the BOC instruction, which allows testing any one of 16 conditions, including status flags, the contents of AC0, and user inputs to the chip. Additional testing capability is provided by the skip instructions, which provide memory or peripheral to register comparisons without altering data. The memory data transfer instructions provide data transfers between the accumulators and memory or peripheral devices. The load with sign extended is provided to convert 8-bit twos complement data to 16-bit data, allowing 16-bit address modification when the 8-bit data length has been selected.

The memory data operate instructions provide operations between the principal working register (AC0) and memory or peripheral data. This includes both binary and BCD arithmetic instructions. The register data transfer instructions provide a very complete set of transfer possibilities between the accumulators, flag register, and stack, and include the capability to load immediate data. Register data operate instructions provide logical and arithmetic operations between any two accumulators. They may be used for address and data modification and to reduce the number of (time-consuming) memory references in a program. The shift and rotate instructions allow 8 different operations which are useful for multiply, divide, bit scanning, and serial input/output operations. The miscellaneous instructions include the capability to set or reset (pulse) any of the 16 bits of the status flag register individually.

The power of the instruction set is further enhanced by a flexible memory addressing scheme that provides three floating memory pages and one fixed page of 256 words each. Instructions which use both direct and indirect memory addressing are included in the instruction set. Three modes of direct memory addressing are available: base page, program counter relative, and index register relative. The direct addressing modes available are summarized in table 2. The mode of addressing is specified by the XR field of the instruction shown in the "Instruction Format" column of table 3.

Indirect addressing consists of first establishing an address in the same fashion as with direct addressing (by either the base page, relative to PC, or indexed [relative to AC2 or AC3] mode). The 16-bit contents of the memory location at this address is then used as the address of the operand, allowing any memory location to be addressed. The Branch Conditions of the INS8900 are listed in table 4 and the Status and Control Flags are listed in table 5.

Table 2. Direct Addressing Modes

XR Field	Addressing Mode	Effective Address
00	Base Page	EA = disp
01	Program Counter Relative	EA = disp + (PC)
10	AC2 Relative (indexed)	EA = disp + (AC2)
11	AC3 Relative (indexed)	EA = disp + (AC3)

Note 1: For base page addressing, disp is positive and in the range of 000 to 255 if BPS = 0, and is a signed number in the range of −128 to +127 if BPS = 1.

Note 2: For relative addressing, disp has a range of −128 to +127.

INS8900 BUFFERED SYSTEM

A block diagram of a fully buffered INS8900 system is illustrated in figure 13. Detailed schematics of the buffered INS8900 Microprocessor, Clock Generator, and Initialize Circuit are illustrated in figures 14, 15, and 16, respectively. The circuits as shown constitute a fully operational CPU module that can be used as the basis for a variety of systems regardless of their application.

NOTE

A 2.0 MHz crystal (Part No. NS209, Package Type HC-6U) for use with the INS8900 may be obtained from:

HALT	Halt	Halt		0 0 0 0 0 0 0 0 0 | 0000000
SFLG	Set Flag (Table 5)	(FR)$_{fc}$ ← 1	5M + E_R	0 0 1 1 | fc | 1
PFLG	Pulse Flag (Table 5)	(FR)$_{fc}$ ← 1, (FR)$_{fc}$ ← 0	6M + E_R	0 0 1 1 | fc | 0
NOP	No Operation	(PC) ← (PC) + 1	4M + E_R	0 1 0 1 1 1 0 0 0 |

Note: M = Machine cycle time = 4 clock periods
n = number of shifts
E_R = Extend time for read cycle
E_W = Extend time for write cycle
External interrupt response time is 7M + E_R plus time to finish current instruction.

Table 4. Branch Conditions

Number	Mnemonic	Condition
0	STFL	Stack full
1	REQ0	(AC0) equal to zero(1)
2	PSIGN	(AC0) has positive sign(2)
3	BIT 0	Bit 0 of AC0 true
4	BIT 1	Bit 1 of AC0 true
5	NREQ0	(AC0) is non-zero(1)
6	BIT 2	Bit 2 AC0 is true
7	CONTIN	CONTIN (continue) input is true
8	LINK	LINK is true
9	IEN	IEN is true
10	CARRY	CARRY is true
11	NSIGN	(AC0) has negative sign(2)
12	OVF	OVF is true
13	JC13	JC13 input is true
14	JC14	JC14 input is true
15	JC15	JC15 input is true

Note 1: If the selected data length is 8 bits, only bits 0-7 of AC0 are tested.
Note 2: Bit 7 is the sign bit (instead of bit 15) if the selected data length is 8 bits.

Table 5. Status and Control Flags

Register Bit	Flag Name	Function
0	"1"	Not used—always logic 1
1	IE1	Interrupt Enable Level 1

ELECTRONIC DISTRIBUTORS MASTER CATALOG

First published to serve you in 1935, The Radio Electronic Master has continuously changed over the years to better meet your needs. Today The Radio Master has become The Electronic Distributors MASTER CATALOG.

The 1978 edition of The Electronic Distributors MASTER CATALOG includes components, systems and subsystems sold through distributors.

It encompasses the following product areas: electronic and electromechanical components, audio and communications equipment, subassembly and panel components, hardware, production equipment and tools, test instrumentation, power sources, wire and cable, and chemicals.

The MASTER CATALOG is divided into four basic sections:

The **GENERAL INDEX** lists manufacturers and products alphabetically, including product cross references. Page numbers are displayed for both manufacturers and products. Manufacturers names are **bold-faced.**

The **MANUFACTURERS' CATALOG SECTION** is a collection of their respective product pages, alphabetically by manufacturer, again including addresses and phone numbers.

The **MANUFACTURERS DIRECTORY** is an alphabetical listing of all manufacturers whose products information is shown. Page numbers are referenced. Sales offices, representatives and distributors are included for many manufacturers.

The **DEALER/DISTRIBUTOR DIRECTORY** geographically lists distribution outlets by state and city. The listings were supplied by manufacturers cataloging in this edition.

INTRODUCING THE μCOM-4 FAMILY — A LINE OF SINGLE CHIP 4-BIT MICROCOMPUTERS

In order to provide the power of microcomputers to the cost sensitive consumer/controller markets, NEC Microcomputers, Inc. offers a family of low cost, powerful 4-bit parallel single chip microcomputers. All of these devices contain on-chip read-only-memory (ROM) for program storage, data storage memory (RAM) and extensive input/output capability.

The family is divided into two applications areas. The μCOM-42 microcomputer's architecture and instruction set is designed to facilitate its use in Electronic Cash Register (ECR)/Scale products. The μCOM-43/44/45 microcomputers are designed for general purpose controller applications and are ideal devices for industrial controls, appliance controls, games, etc.

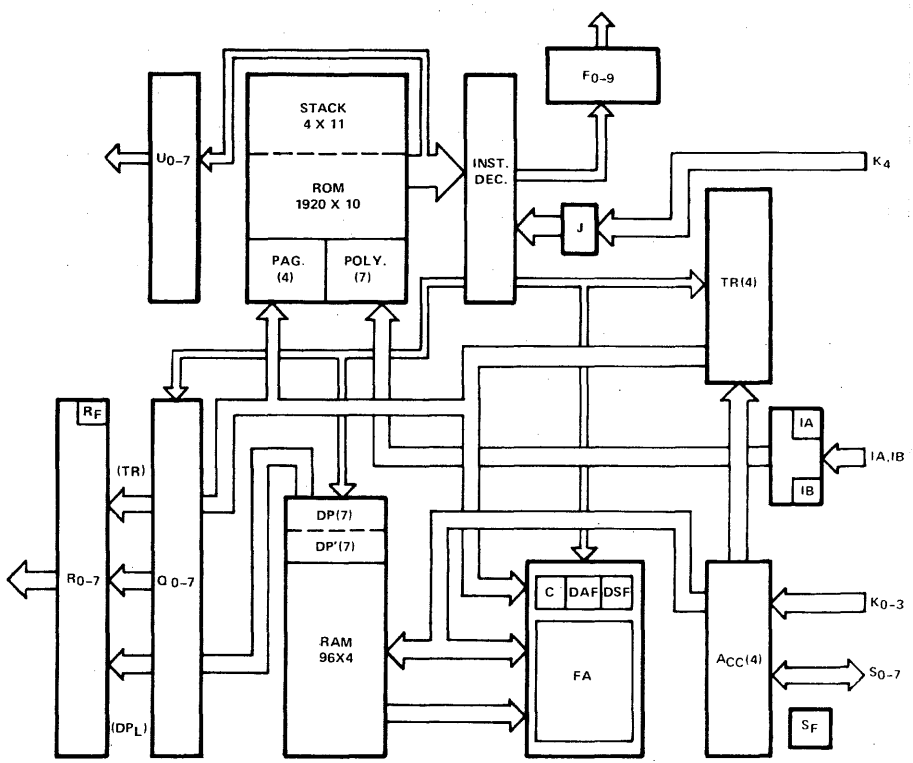
Both families are supported by NEC's high volume production capability, evaluation chips and evaluation kits, PDA-80 software development system and extensive documentation.

μCOM-42

DESCRIPTION

The μCOM-42 (Part No. μPD548C) is a single chip microcomputer that is ideally suited for Electronic Cash Register (ECR), Point of Sale (POS) and Electronic Scale applications.

Containing a 4-bit Parallel ALU, ROM for program storage and RAM for data storage, the μCOM-42 provides an economical and simple solution to many Vending/Calculating requirements.



Because of its extensive instruction set and five input/output ports, the μCOM-42 is capable of controlling an 8 x 4 keyboard, an 8 digit display and low cost ECR-type printers.

Finally, the on-chip RAM space can be augmented by an external μPD5101 CMOS RAM (256 x 4 bits) for applications requiring low power data retention.

FEATURES

- Stand alone 4-bit microcomputer
- All 72 instructions are single byte
- 10 μsec instruction cycle
- 1920 x 10-bit program memory (ROM)
- 96 x 4-bit data memory (RAM)
- 4-level stack
- 2 interrupt request lines
- I/O compatible with TTL
- 10 discrete output ports ($F_0 - F_9$)
- Two 8-bit output ports ($U_0 - U_7$, $R_0 - R_7$)
- One 4-bit input port ($K_0 - K_3$)
- One 4-bit input/output port ($S_0 - S_3$)
- One single bit testable input port (K_4)
- Single phase TTL level clock (200 KHz max)
- Single supply, -10V PMOS technology
- 42 pin plastic dual-in-line package

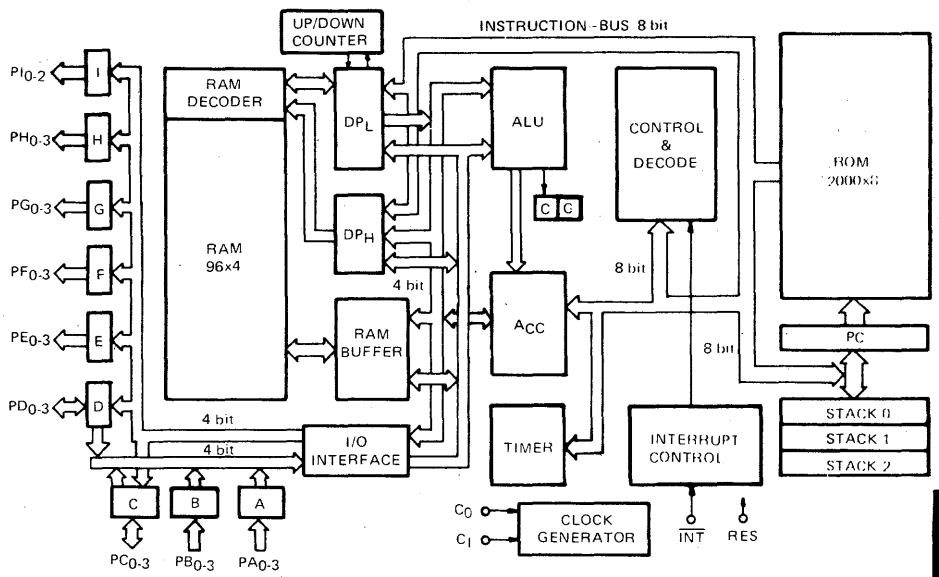
μCOM-43

DESCRIPTION

The μCOM-43 (Part No. μPD546C) is a 4-bit parallel microcomputer that is especially suited for a wide range of low cost, sophisticated controller applications.

The μPD546C contains all the functional blocks necessary to enable its use for both industrial and non-industrial controller applications. These blocks include: a 4-bit parallel ALU; 2K by 8-bit ROM for program storage; 96 x 4-bit RAM for data storage; 35 input/output lines; a programmable interval timer; interrupt capability; and on-board clock generator.



The 80 instructions of the μCOM-43 are designed to perform controller oriented functions and for efficient use of the program memory space. These 80 instructions include a number of multi-function instructions, powerful I/O instructions including single bit manipulation, and test-and-skip instructions for conditional processing.

Thus, the μCOM-43's large ROM memory, extensive I/O, and other hardware features in combination with its powerful instruction set opens up new areas for inexpensive yet sophisticated controllers.

FEATURES

- Stand alone 4-bit microcomputer for control applications
- 80 powerful instructions capable of: binary addition; decimal addition and subtraction; and logical operations
- 10 μsec instruction cycle
- 2000 x 8-bit program memory (ROM)
- 96 x 4-bit data memory (RAM)
- 35 input/output lines consisting of: two 4-bit input ports, two 4-bit input/output ports, four 4-bit output ports, one 3-bit output port. All capable of both single bit manipulation and 4-bit parallel processing
- 3-level stack
- Six 4-bit working registers
- Hardware interrupt including enable/disable capability
- On-chip programmable interval timer
- On-chip clock generator
- Open drain, TTL compatible outputs
- Single supply, -10V PMOS technology
- 42 pin plastic dual-in-line package

BLOCK DIAGRAM

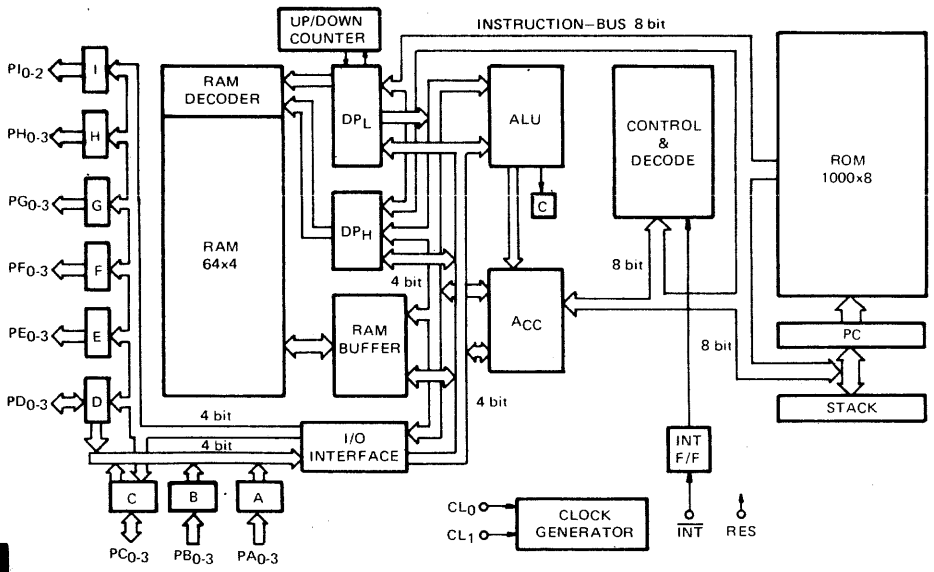
μCOM-44

DESCRIPTION

The μCOM-44 (Part No. μPD547C) is a 4-bit parallel microcomputer that is ideally suited for a wide range of low cost, general purpose controller applications.

The μPD546C contains all the functional blocks needed for a low cost, stand alone, high volume controller. These blocks include: a 4-bit parallel ALU; 1K by 8-bit ROM for program storage; 64 by 4-bit RAM for data storage; 35 input/output lines; interrupt capability and an on-board clock generator.



The 58 instructions of the μCOM-44 are designed to perform controller oriented functions and for efficient use of the program memory space. These 58 instructions include a number of multifunctional instructions, powerful I/O instructions including single bit manipulation, and test-and-skip instructions for conditional processing.

The μCOM-44 is ideally suited for consumer/industrial controller functions because of its extensive I/O, on-board ROM/RAM space and its powerful instruction set.

FEATURES

- Stand alone 4-bit microcomputer for control applications
- 58 powerful instructions capable of: binary addition; decimal addition and subtraction; and logical operations
- 10 μsec instruction cycle
- 1000 x 8-bit program memory (ROM)
- 64 x 4-bit data memory (RAM)
- 35 Input/Output lines consisting of: two 4-bit input ports; two 4-bit input/output ports; four 4-bit output ports, one 3-bit output port. All capable of both single bit manipulation and 4-bit parallel processing.
- Single level stack
- On-chip clock generator
- Open drain, TTL compatible outputs
- Single supply, -10V PMOS technology
- 42 pin plastic dual-in-line package

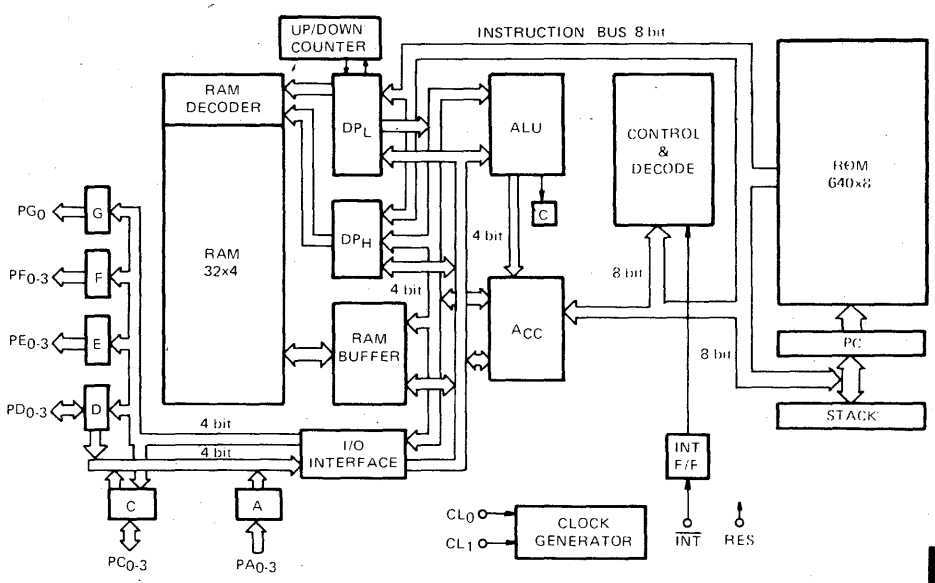
μCOM-45

DESCRIPTION

The μCOM-45 (Part No. μPD550C) is a single chip microcomputer designed for extremely low cost, general purpose controller/consumer/appliance applications.

The μPD550C contains all the system blocks necessary to build an inexpensive, yet fully functional controller. The blocks include: a 4-bit parallel ALU; 640 by 8-bit ROM for program storage; 32 by 4-bit RAM for data storage; 21 input/output lines; interrupt capability and an on-board clock generator.



The 58 instructions of the μCOM-45 are designed to perform controller oriented functions and for efficient use of the program memory space. These 58 instructions include a number of multifunctional instructions, powerful I/O instructions including single bit manipulation, and test-and-skip instructions for conditional processing.

The μCOM-45 opens up entire new areas of controller applications because of its extremely low cost and powerful functions.

FEATURES

- Stand alone 4-bit microcomputer for consumer/control applications
- 58 powerful instructions capable of: binary addition; decimal addition and subtraction; and logical operations
- 10 μsec instruction cycle
- 640 x 8-bit program memory (ROM)
- 32 x 4-bit data memory (RAM)
- 21 Input/Output lines consisting of: one 4-bit input port; two 4-bit input/output ports; two 4-bit output ports; one 1-bit output port. All capable of both single bit manipulation and 4-bit parallel processing.
- Single level stack
- On-chip clock generator
- Open drain, TTL compatible outputs capable of -35V
- Single Supply, -10V PMOS technology
- 28 pin plastic dual-in-line package

μCOM-4 FAMILY DEVELOPMENT TOOLS

The μCOM-4 microcomputer family is fully supported with all the necessary hardware and software development tools. These tools include assemblers, evaluation chips and evaluation kits.

For software development, cross-assemblers that run on our 8080A-based PDA-80 are available along with support documentation. The PDA-80 allows the user to program PROMs directly without having to use a paper tape medium.

For hardware and software development, evaluation kits and evaluation chips are available. The EVACHIPS (μPD555D for the μCOM-42 and μPD556D for the μCOM-43/44/45) have all the functional capabilities of their production equivalents, except they do not contain on-chip ROM. Instead they have the ability to address external memory. In addition, they give the designer the ability to single step through his program in order to ease debugging.

The evaluation kits (EVAKIT-42 and EVAKIT-43), using the appropriate EVACHIP, provide the designer with a single pc board containing: LED's for display of internal registers and instruction code; switches for setting breakpoints; on-board PROM sockets; and reset and single-step capability. The combination of EVAKIT and EVACHIP give the μCOM-4 system designer all the tools needed for initial design/debugging and prototype fabrication.

EVAKIT-42 μCOM-42 PROTOTYPING BOARD

DESCRIPTION

The EVAKIT-42 is a single board prototyping package for both hardware and software debugging of the μCOM-42 one-chip microcomputer system.

The heart of the EVAKIT-42 is the μPD555D evaluation chip which provides the same functionality as the μPD548C. Unlike the μCOM-42, the μPD555D does not contain a read only memory, but provides addressing capability to external memories instead.

The EVAKIT-42 also includes sockets for 2K bytes of EEPROM memory, LED displays to show register contents, switches for breakpoint and mode selection, and control logic for single step operation, all residing on a single printed circuit board.

FEATURES

- Single Step Execution
- Display of Instruction Code to be Executed
- Display of Contents of Program Counter
- BREAK Function at any Address
- Display of Contents of Accumulator and S Port
- Selection of Program Memory, On-Board PROM or External PROM

Product Name	EVAKIT-42
LSI's Used	CPU μPD555D PROM μPD454D (up to 16)
Clock Frequency	100 KHz to 200 KHz
Program Capacity	1920 Words (10 Bits/Word)
Operating Temperature	0°C to 45°C
Power Supplies	+7V ± 5% 0.6A (Max) −5V ± 5% 1.0A (Max) −10V ± 5% 0.2A (Max)
Dimension	240 mm x 310 mm
Connector	100-Pin Double-Sided PC Edge Connector with 0.125 inch (3.175 mm) Contact Center

EVAKIT-43 μCOM-43/44/45 PROTOTYPING BOARD

DESCRIPTION

The EVAKIT-43 is a single board prototyping package for both hardware and software debugging of the μCOM-43/44/45 one-chip microcomputer systems.

The heart of the EVAKIT-43 is the μPD556D evaluation chip which provides the same functionality as the μCOM-43 (μPD546D). This includes full I/O capability, on-chip timer and clock generator. Unlike the μPD546, which contains on-chip ROM, the μPD556 provides addressing capability to external memory instead.

The EVAKIT-43 also includes: sockets for 2K bytes of EEPROM (in either 256 or 1K byte increments); LED displays to show the contents of the program counter, accumulator, data pointer and instruction register; switches for breakpoint and mode selection; and control logic for single step operation.

FEATURES

- Single Step Execution
- Internal Register Display
- BREAK Function at any Address
- Selection of Program Memory, On-Board PROM or External PROM

MAJOR SPECIFICATIONS

Product Name	EVAKIT-43
LSI's Used	CPU μPD556D PROM μPD454D or μPD458D
Clock Frequency	100 KHz to 200 KHz
Program Capacity	2K Bytes
Operating Temperature	0°C to 45°C
Power Supplies	+5V ± 5% 0.8A (Max) −5V ± 5% 0.1A (Max)
Dimension	251 mm x 324 mm
Connector	100-Pin Double-Sided PC Edge Connector with 0.125 inch (3.175 mm) Contact Center

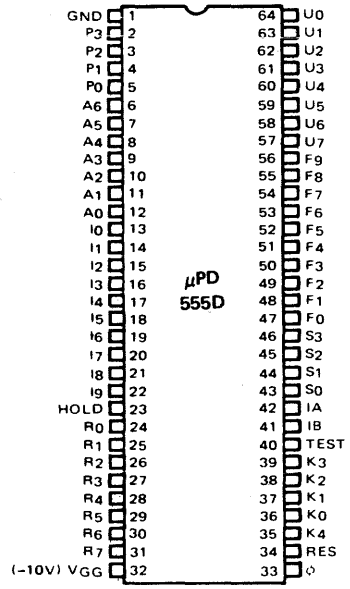
EVACHIP-42



DESCRIPTION

The EVACHIP-42 (Part No. μPD555D) is an evaluation chip for the μCOM-42 single chip microcomputer. Designed to be used for both hardware and software debugging, the EVACHIP-42 is functionally equivalent to the μCOM-42, except that it does not contain on-chip ROM. Instead, it is able to address external memory and also has HOLD capability to enable single step operation of the program being evaluated.

FEATURES

- 4-Bit Parallel Processor
- Full 72 Instruction Set of μCOM-42
- 10 μsec Instruction Cycle
- Capable of Addressing 1920 x 10-Bits of External Program Memory
- HOLD Capability
- Full Functionality of μCOM-42
- Single Supply, −10V PMOS Technology
- 64 Pin Ceramic Dual-in-Line Package

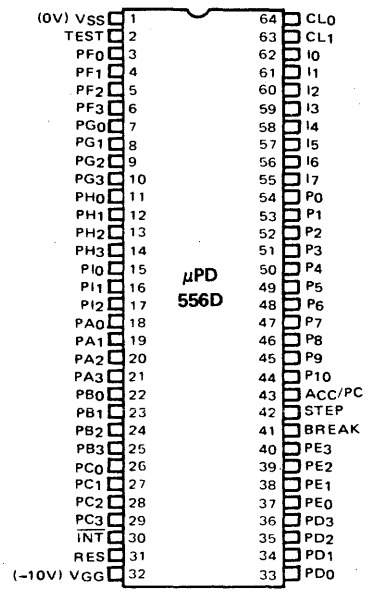
PIN CONFIGURATION

PIN NAMES

$P_0 - P_3$	Page Output
$A_0 - A_6$	Address Output
$I_0 - I_9$	Instruction Input
HOLD	HOLD Input
$R_0 - R_7$	Output Port R
φ	Clock Input
RES	Reset Input
K4	K4 Test Input Line
$K_0 - K_3$	K Input Port
TEST	IC Test Input
IA, IB	Interrupt Input
$S_0 - S_3$	Input/Output Port S
$F_0 - F_9$	Output Port F
$U_0 - U_7$	Output Port U

EVACHIP-43

DESCRIPTION



The EVACHIP-43 (Part No. μPD556D) is an evaluation chip for the μCOM-43/44/45 single chip microcomputers. Designed to be used for both hardware and software debugging, the EVACHIP-43 is functionally equivalent to the μCOM-43, except that it does not contain on-chip ROM. Instead, it is able to address external memory. In addition, in order to facilitate debugging, the μPD556 is capable of displaying the contents of the internal accumulator and data pointer and of being single stepped.

When the μPD556 is being used to evaluate μCOM-44/45 designs, the external memory capacity should be restricted to that of the respective on-chip ROM and the instructions used should be restricted to the 58 comprising the μCOM-44/45 instruction set.

FEATURES

- 4-bit Parallel Processor
- Full 80 Instruction Set of μCOM-43
- 10 μsec Instruction Cycle
- Capable of Addressing 2K x 8-Bits of External Program Memory
- Single Step Capability
- Full Functionality of μCOM-43
- Single Supply, −10V PMOS Technology
- 64 Pin Ceramic Dual-in-Line Package

PIN CONFIGURATION

PIN NAMES

$PF_0 - PF_3$	Output Port F
$PG_0 - PG_3$	Output Port G
$PH_0 - PH_3$	Output Port H

PDA-80 PROGRAM DEVELOPMENT AID

DESCRIPTION

The PDA-80 is a self-contained microcomputer development system providing unique features for rapid development of μCOM-4 Family software. A full software package is provided for program generation. This package includes: a resident MONITOR for program loading and system control; an EDITOR program for generating and modifying source language programs; ASSEMBLER programs for converting source programs to object programs and for generating symbol tables and program listings for documentation and debugging; and DIAGNOSTIC programs for testing the proper operation of the PDA-80 itself.

The PDA-80 shortens the design cycle, thus cutting your product development costs and getting your product on the market fast. One of its features providing shortened design time is the integral EEPROM PROGRAMMER. This allows the prototype designer to quickly reprogram and debug his hardware without the need for time-wasting UV erasure. (NEC's EEPROMs are available in 1K by 8 (μPD458) or 256 by 8 (μPD454) configurations with typical erase time of 60 sec and program time of 30 ms per byte).

Finally, the PDA-80 is available with a full line of peripherals to further speed program generation and software debugging. These include hard copy consoles of either 30 or 120 cps and the choice of either a floppy disk system or a high speed paper tape reader/punch. And it is also a full-blown 8080A hardware/software development system!

FEATURES

- Integral EEPROM Programmer
- 8080A Based
- TTY or RS-232C Compatible
- Up to 56K of RAM
- Self Diagnostic Programs
- Full Line of High Speed Peripherals Available
- Cross Assemblers for all μCOM-4 Family Processors

SPECIFICATION

Cabinet	15 x 17 x 8 inches (37 x 44 x 20 cm)
Power	100/117 Vac 60 Hz
Operating Temperature	0 to +55°C
Humidity Range	0 to 90%
Weight	45 pounds (20.5 Kg)

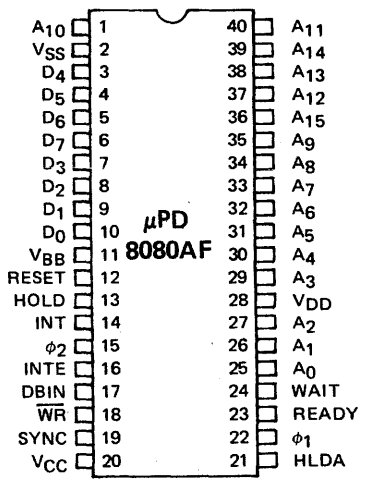
μPD8080AF 8-BIT N-CHANNEL MICROPROCESSOR FAMILY



DESCRIPTION

The μPD8080AF is a complete 8-bit parallel processor for use in general purpose digital computer systems. It is fabricated on a single LSI chip using N-channel silicon gate MOS process, which offers much higher performance than conventional microprocessors (1.28 μs minimum instruction cycle). A complete microcomputer system is formed when the μPD8080AF is interfaced with I/O ports (up to 256 input and 256 output ports) and any type or speed of semiconductor memory. It is available in a 40 pin ceramic or plastic package.

FEATURES

- 78 Powerful Instructions
- Three Devices – Three Clock Frequencies
  μPD8080AF – 2.0 MHz
  μPD8080AF-2 – 2.5 MHz
  μPD8080AF-1 – 3.0 MHz
- Direct Access to 64K Bytes of Memory with 16-Bit Program Counter
- 256 8-Bit Input Ports and 256 8-Bit Output Ports
- Double Length Operations Including Addition
- Automatic Stack Memory Operation with 16-Bit Stack Pointer
- TTL Compatible (Except Clocks)
- Multi-byte Interrupt Capability
- **Fully** Compatible with Industry Standard 8080A
- Available in either Plastic or Ceramic Package

PIN CONFIGURATION

Rev/1

©IC MASTER 1978

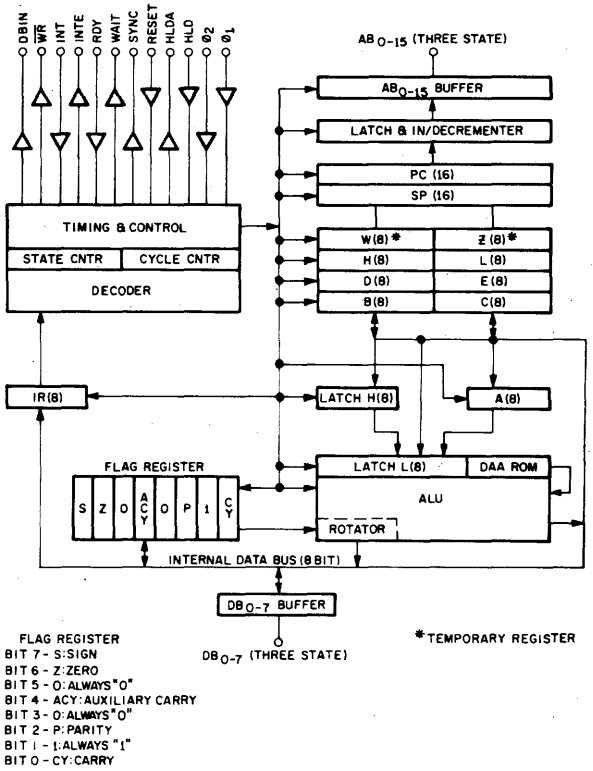
FUNCTIONAL DESCRIPTION

The μPD8080AF contains six 8-bit data registers, an 8-bit accumulator, four testable flag bits, and an 8-bit parallel binary arithmetic unit. The μPD8080AF also provides decimal arithmetic capability and it includes 16-bit arithmetic and immediate operators which greatly simplify memory address calculations, and high speed arithmetic operations.

The μPD8080AF utilizes a 16-bit address bus to directly address 64K bytes of memory, is fully TTL compatible (1.9 mA), and utilizes the following addressing modes: Direct; Register; Register Indirect; and Immediate.

The μPD8080AF has a stack architecture wherein any portion of the external memory can be used as a last in/first out (LIFO) stack to store/retrieve the contents of the accumulator, the flags, or any of the data registers.

The μPD8080AF also contains a 16-bit stack pointer to control the addressing of this external stack. One of the major advantages of the stack is that multiple level interrupts can easily be handled since complete system status can be saved when an interrupt occurs and then restored after the interrupt is complete. Another major advantage is that almost unlimited subroutine nesting is possible.



This processor is designed to greatly simplify system design. Separate 16-line address and 8-line bidirectional data busses are employed to allow direct interface to memories and I/O ports. Control signals, requiring no decoding, are provided directly by the processor. All busses, including the control bus, are TTL compatible.

Communication on both the address lines and the data lines can be interlocked by using the HOLD input. When the Hold Acknowledge (HLDA) signal is issued by the processor, its operation is suspended and the address and data lines are forced to be in the FLOATING state. This permits other devices, such as direct memory access channels (DMA), to be connected to the address and data busses.

The μPD8080AF has the capability to accept a multiple byte instruction upon an interrupt. This means that a CALL instruction can be inserted so that any address in the memory can be the starting location for an interrupt program. This allows the assignment of a separate location for each interrupt operation, and as a result no polling is required to determine which operation is to be performed.

NEC offers three versions of the μPD8080AF. These processors have all the features of the μPD8080AF except the clock frequency ranges from 2.0 MHz to 3.0 MHz. These units meet the performance requirements of a variety of systems while maintaining software and hardware compatibility with other 8080A devices.

BLOCK DIAGRAM

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
1, 25-27, 29-40	$A_{15} - A_0$	Address Bus (output three-state)	The address bus is used to address memory (up to 64K 8-bit words) or specify the I/O device number (up to 256 input and 256 output devices). A_0 is the least significant bit.
2	V_{SS}	Ground (input)	Ground
3-10	$D_7 - D_0$	Data Bus (input/ output three-state)	The bidirectional data bus communicates between the processor, memory, and I/O devices for instructions and data transfers. During each sync time, the data bus contains a status word that describes the current machine cycle. D_0 is the least significant bit.
11	V_{BB}	V_{BB} Supply Voltage (input)	-5V ± 5%
12	RESET	Reset (input)	If the RESET signal is activated, the program counter is cleared. After RESET, the program starts at location 0 in memory. The INTE and HLDA flip-flops are also reset. The flags, accumulator, stack pointer, and registers are not cleared. (Note: External synchronization is not required for the RESET input signal which must be active for a minimum of 3 clock periods.)
13	HOLD	Hold (input)	HOLD requests the processor to enter the HOLD state. The HOLD state allows an external device to gain control of the μPD8080AF address and data buses as soon as the μPD8080AF has completed its use of these buses for the current machine cycle. It is recognized under the following conditions: • The processor is in the HALT state. • The processor is in the T_2 or T_W stage and the READY signal is active. As a result of entering the HOLD state, the ADDRESS BUS ($A_{15} - A_0$) and DATA BUS ($D_7 - D_0$) are in their high impedance state. The processor indicates its state on the HOLD ACKNOWLEDGE (HLDA) pin.
14	INT	Interrupt Request (input)	The μPD8080AF recognizes an interrupt request on this line at the end of the current instruction or while halted. If the μPD8080AF is in the HOLD state, or if the Interrupt Enable flip-flop is reset, it will not honor the request.
15	ϕ_2	Phase Two (input)	Phase two of processor clock.
16	INTE (1)	Interrupt Enable (output)	INTE indicates the content of the internal interrupt enable flip-flop. This flip-flop is set by the Enable (EI) or reset by the Disable (DI) interrupt instructions and inhibits interrupts from being accepted by the processor when it is reset. INTE is automatically reset (disabling further interrupts) during T_1 of the instruction fetch cycle (M_1) when an interrupt is accepted and is also reset by the RESET signal.
17	DBIN	Data Bus In (output)	DBIN indicates that the data bus is in the input mode. This signal is used to enable the gating of data onto the μPD8080AF data bus from memory or input ports.
18	$\overline{WR}$	Write (output)	$\overline{WR}$ is used for memory WRITE or I/O output control. The data on the data bus is valid while the $\overline{WR}$ signal is active ($\overline{WR}$ = 0).
19	SYNC	Synchronizing Signal (output)	The SYNC signal indicates the beginning of each machine cycle.
20	V_{CC}	V_{CC} Supply Voltage (input)	+5V ± 5%
21	HLDA	Hold Acknowledge (output)	HLDA is in response to the HOLD signal and indicates that the data and address bus will go to the high impedance state. The HLDA signal begins at: • T_3 for READ memory or input operations. • The clock period following T_3 for WRITE memory or OUTPUT operations. In either case, the HLDA appears after the rising edge of ϕ_1 and high impedance occurs after the rising edge of ϕ_2.
22	ϕ_1	Phase One (input)	Phase one of processor clock.
23	READY	Ready (input)	The READY signal indicates to the μPD8080AF that valid memory or input data is available on the μPD8080AF data bus. READY is used to synchronize the processor with slower memory or I/O devices. If after sending an address out, the μPD8080AF does not receive a high on the READY pin, the μPD8080AF enters a WAIT state for as long as the READY pin is low. (READY can also be used to single step the processor.)
24	WAIT	Wait (output)	The WAIT signal indicates that the processor is in a WAIT state.
28	V_{DD}	V_{DD} Supply Voltage (input)	+12V ± 5%

Note: (1) After the EI instruction, the μPD8080AF accepts interrupts on the second instruction following the EI. This allows proper execution of the RET instruction if an interrupt operation is pending after the service routine.

Notes Continued:

④ The following are relevant when interfacing the μPD8080AF to devices having V_{IH} = 3.3V.

a. Maximum output rise time from 0.8V to 3.3V = 100 ns at C_L = SPEC.

b. Output delay when measured to 3.0V = SPEC +60 ns at C_L = SPEC.

c. If $C_L \neq$ SPEC, add 0.6 ns/pF if $C_L > C_{SPEC}$, subtract 0.3 ns/pF (from modified delay) if $C_L < C_{SPEC}$.

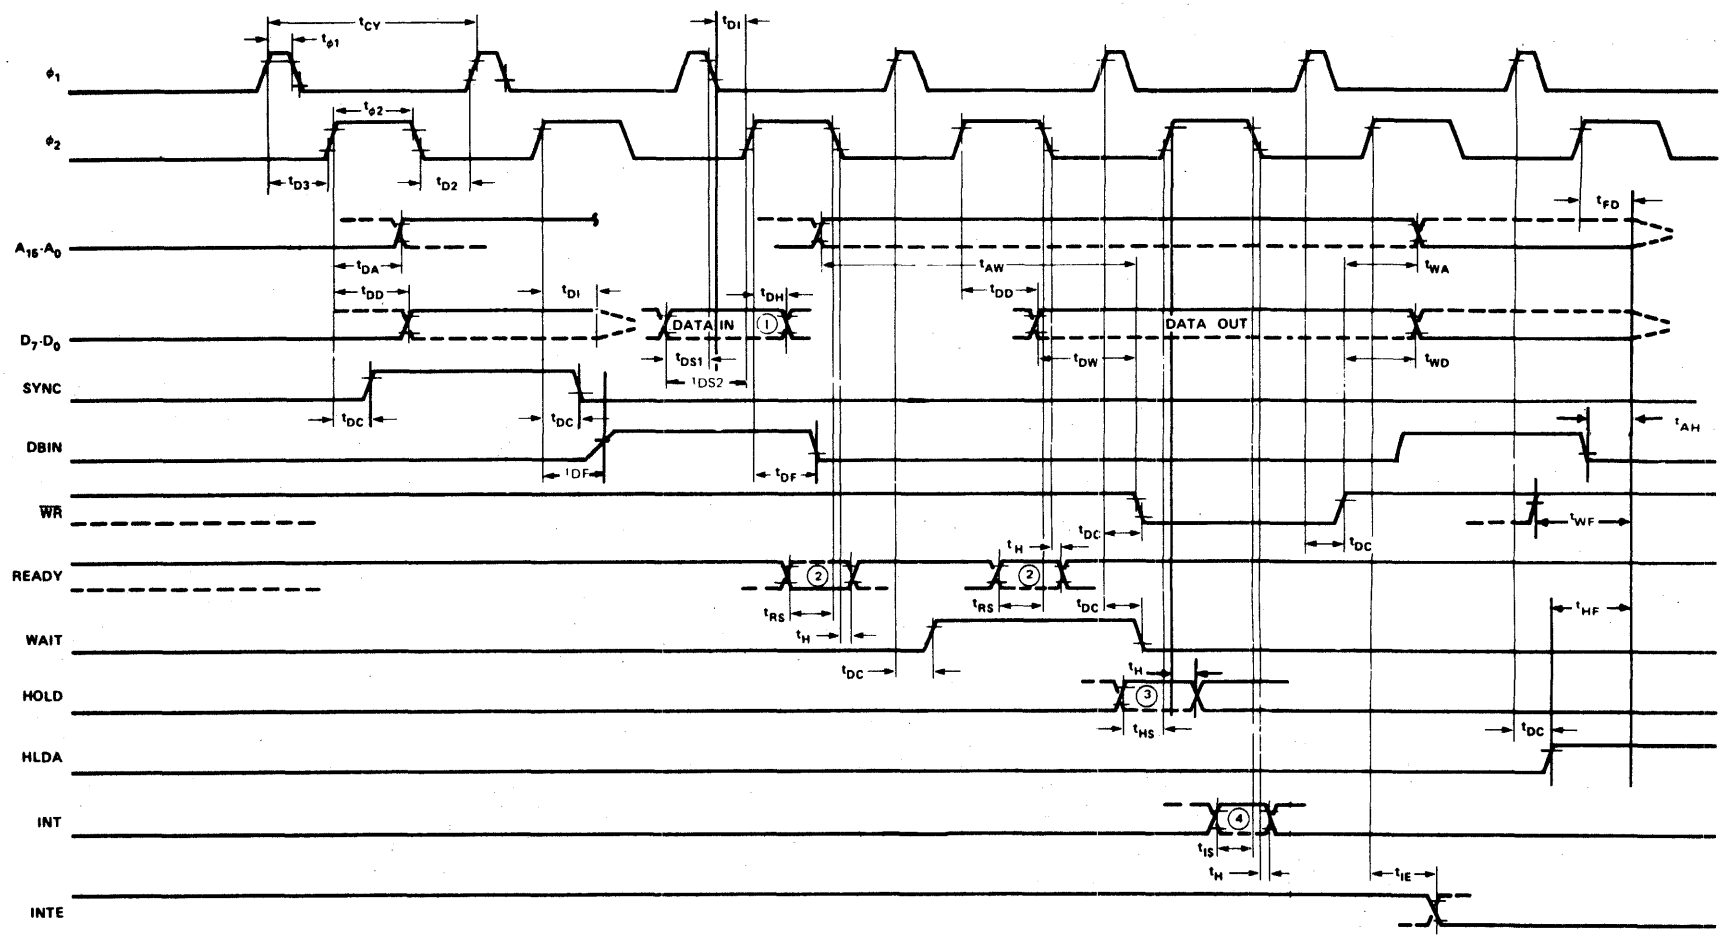
Address Hold Time after DBIN during HLDA	t_{AH} ②	−20			nsec	

Notes Continued: ⑤

Device	t_{AW}
μPD8080AF	$2t_{CY} - t_{D3} - t_{r\phi2} - 140$
μPD8080AF-2	$2t_{CY} - t_{D3} - t_{r\phi2} - 130$
μPD8080AF-1	$2t_{CY} - t_{D3} - t_{r\phi2} - 110$

⑥

Device	t_{DW}
μPD8080AF	$t_{CY} - t_{D3} - t_{r\phi2} - 170$
μPD8080AF-2	$t_{CY} - t_{D3} - t_{r\phi2} - 170$
μPD8080AF-1	$t_{CY} - t_{D3} - t_{r\phi2} - 150$



⑦ If not HLDA, $t_{WD} = t_{WA} = t_{D3} + t_{r\phi2} + 10$ ns. If HLDA, $t_{WD} = t_{WA} = t_{WF}$.

⑧ $t_{HF} = t_{D3} + t_{r\phi2} - 50$ ns.

⑨ $t_{WF} = t_{D3} + t_{r\phi2} - 10$ ns.

TIMING WAVEFORMS ⑤ ⑥

Notes: ① Data in must be stable for this period during DBIN • T_3. Both t_{DS1} and t_{DS2} must be satisfied.

② Ready signal must be stable for this period during T_2 or T_W. (Must be externally synchronized.)

③ Hold signal must be stable for this period during T_2 or T_W when entering hold mode, and during T_3, T_4, T_5 and T_{WH} when in hold mode. (External synchronization is not required.)

④ Interrupt signal must be stable during this period of the last clock cycle of any instruction in order to be recognized in the following instruction. (External synchronization is not required.)

⑤ This timing diagram shows timing relationships only; it does not represent any specific machine cycle.

⑥ Timing measurements are made at the following reference voltages: CLOCK "1" = 8.0V, "0" = 1.0V; INPUTS "1" = 3.3V; "0" = 0.8V; OUTPUTS "1" = 2.0V, "0" = 0.8V.

©IC MASTER 1978

INSTRUCTION SET

The instruction set includes arithmetic and logical operators with direct, register, indirect, and immediate addressing modes.

Move, load, and store instruction groups provide the ability to move either 8 or 16 bits of data between memory, the six working registers and the accumulator using direct, register, indirect, and immediate addressing modes.

The ability to branch to different portions of the program is provided with direct, conditional, or computed jumps. Also the ability to call and return from subroutines is provided both conditionally and unconditionally. The RESTART (or single byte call instruction) is useful for interrupt vector operation.

Conditional jumps, calls and returns execute based on the state of the four testable flags (Sign, Zero, Parity and Carry). The state of each flag is determined by the result of the last instruction executed that affected flags. (See Instruction Set Table.)

The Sign flag is set (High) if bit 7 of the result is a "1"; otherwise it is reset (Low). The Zero flag is set if the result is "0"; otherwise it is reset. The Parity flag is set if the modulo 2 sum of the bits of the result is "0" (Even Parity); otherwise (Odd Parity) it is reset. The Carry flag is set if the last instruction resulted in a carry or a borrow out of the most significant bit (bit 7) of the result; otherwise it is reset.

In addition to the four testable flags, the μPD8080AF has another flag (ACY) that is not directly testable. It is used for multiple precision arithmetic operations with the DAA instruction. The Auxiliary Carry flag is set if the last instruction resulted in a carry or a borrow from bit 3 into bit 4; otherwise it is reset.

Double precision operators such as stack manipulation and double add instructions extend both the arithmetic and interrupt handling capability of the μPD8080AF. The ability to increment and decrement memory, the six general registers and the accumulator are provided as well as extended increment and decrement instructions to operate on the register pairs and stack pointer. Further capability is provided by the ability to rotate the accumulator left or right through or around the carry bit.

Input and output may be accomplished using memory addresses as I/O ports or the directly addressed I/O provided for in the μPD8080AF instruction set.

The special instruction group completes the μPD8080AF instruction set: NOP, HALT stop processor execution; DAA provides decimal arithmetic capability; STC sets the carry flag; CMC complements it; CMA complements the contents of the accumulator; and XCHG exchanges the contents of two 16-bit register pairs directly.

DATA AND INSTRUCTION FORMATS

Data in the μPD8080AF is stored as 8-bit binary integers. All data/instruction transfers to the system data bus are in the following format:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0

MSB DATA WORD LSB

Instructions are one, two, or three bytes long. Multiple byte instructions must be stored in successive locations of program memory. The address of the first byte is used as the address of the instruction.

		TYPICAL INSTRUCTIONS
One Byte Instructions		
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	Register to register, memory reference, arithmetic or logical, rotate, return, push, pop, enable, or disable interrupt instructions
Two Byte Instructions		
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	Immediate mode or I/O instructions
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OPERAND	
Three Byte Instructions		
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	Jump, call or direct load and store instructions
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	LOW ADDRESS OR OPERAND 1	
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	HIGH ADDRESS OR OPERAND 2

INSTRUCTION CYCLE TIMES

One to five machine cycles ($M_1 - M_5$) are required to execute an instruction. Each machine cycle involves the transfer of an instruction or data byte into the processor or a transfer of a data byte out of the processor (the sole exception being the double add instruction). The first one, two or three machine cycles obtain the instruction from the memory or an interrupting I/O controller. The remaining cycles are used to execute the instruction. Each machine cycle requires from three to five clock times ($T_1 - T_5$). During $\phi 1 \cdot$ SYNC of each machine cycle, a status word that identifies the type of machine cycle is available on the data bus.

Execution times and machine cycles used for each type of instruction are shown below.

INSTRUCTION	MACHINE CYCLES EXECUTED	CLOCK TIMES (MIN/MAX)
RST X and PUSH RP	PCR5 (1) SPW3 (5) SPW3 (5)	11

Machine Cycle Symbol Definition

XX Y Z (N)
- XX: Status word defining type of machine cycle (See Status Word Chart)
- Y: Number of clocks for this machine cycle
- Z: R = Read cycle — data into processor; W = Write cycle — data out of processor; X = No data transfer; PC = Program Counter used as address
- (N)

XX
- HL = Registers H and L used as address
- BC = Registers B and C used as address
- DE = Registers D and E used as address
- SP = Stack Pointer used as address
- BB = Byte 2 and 3 used as address
- AB = Byte 2 used as address

Underlined (XXYZ(N)) indicates machine cycle is executed if condition is True.

©IC MASTER 1978

STATUS INFORMATION DEFINITION

SYMBOLS	DATA BUS BIT	DEFINITION
INTA ①	D_0	Acknowledge signal for INTERRUPT request. Signal should be used to gate a restart or CALL instruction onto the data bus when DBIN is active.
$\overline{WO}$	D_1	Indicates that the operation in the current machine cycle will be a WRITE memory or OUTPUT function ($\overline{WO}$ = 0). Otherwise, a READ memory or INPUT operation will be executed.
STACK	D_2	Indicates that the address bus holds the pushdown stack address from the Stack Pointer.
HLTA	D_3	Acknowledge signal for HALT instruction.
OUT	D_4	Indicates that the address bus contains the address of an output device and the data bus will contain the output data when $\overline{WR}$ is active.
M_1	D_5	Provides a signal to indicate that the CPU is in the fetch cycle for the first byte of an instruction.
INP ①	D_6	Indicates that the address bus contains the address of an input device and the input data should be placed on the data bus when DBIN is active.
MEMR ①	D_7	Designates that the data bus will be used for memory read data.

Note: ① These three status bits can be used to control the flow of data onto the μPD8080AF data bus.

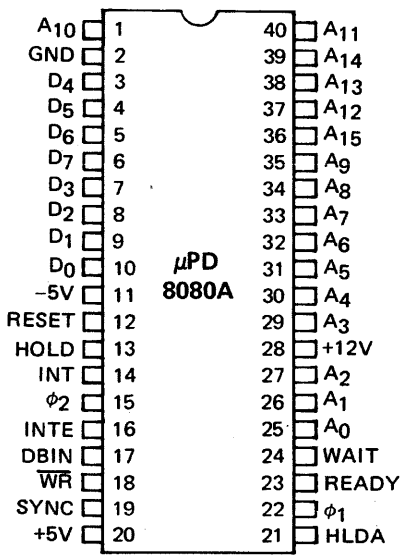
8-BIT N-CHANNEL MICROPROCESSOR

DESCRIPTION

The μPD8080A is a complete 8-bit parallel processor for use in general purpose digital computer systems, which offers higher performance than conventional 8080A microprocessors. It is fabricated on a single LSI chip using N-channel silicon gate MOS process.

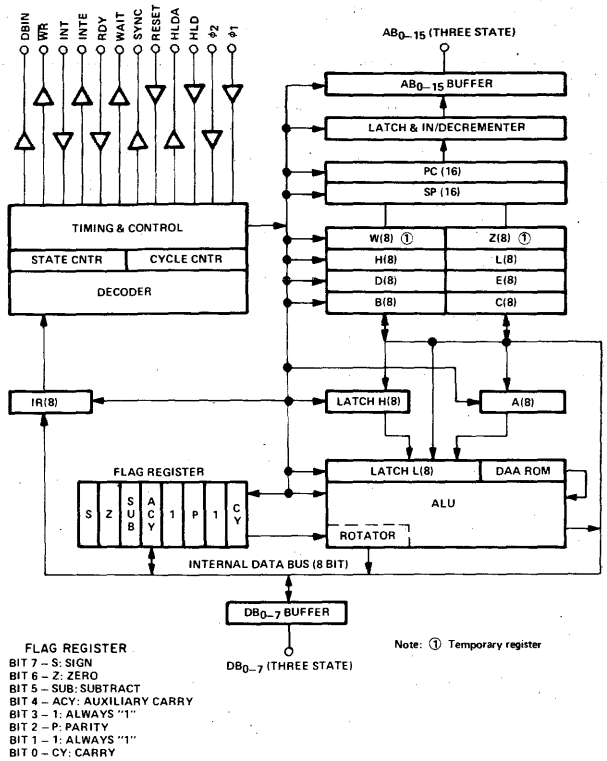


This processor is designed to greatly simplify system design. Separate 16-line address and 8-line bidirectional data busses are employed to allow direct interface to memories and I/O ports. Control signals, requiring no decoding, are provided directly by the processor. All busses, including the control bus, are TTL and CMOS compatible.

The μPD8080A has the capability to accept a multiple byte instruction upon an interrupt. This means that a CALL instruction can be inserted so that any address in the memory can be the starting location for an interrupt program. This can be accomplished without auxilliary circuit because INTA is active for all three bytes of the CALL instruction. Another important feature is that the decimal adjust accumulator instruction operates correctly after subtraction as well as after addition; thus BCD subtraction can be performed at the same speed as BCD addition.

FEATURES

- Software and Pin Compatible with Industry Standard 8080A
- Clock Frequency – 2.0 MHz
- Equivalent to the μPD8080AF with Enhancements
- Direct BCD Subtraction as well as Addition
- MOV r, r Executes in 4 Clock Cycles
- Interrupt Acknowledge is Active for 3 Byte Instructions such as CALL
- Available in a 40-pin Ceramic Package



PIN CONFIGURATION

Rev/1

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	−10°C to +70°C
Storage Temperature	−65°C to +150°C
All Input or Output Voltages	−0.3 to +20 Volts ①
V_{CC}, V_{DD} and V_{SS}	−0.3 to +20 Volts ①
Power Dissipation	1.5W

Note: ① Relative to V_{BB}

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

*T_a = 25°C

DC CHARACTERISTICS

T_a = −10°C to 70°C, V_{DD} = +12V ± 5%, V_{CC} = +5V ± 5%, V_{BB} = −5V ± 5%, V_{SS} = GND, unless otherwise specified.

PARAMETER	SYMBOL	LIMITS MIN	LIMITS TYP	LIMITS MAX	UNIT	TEST CONDITIONS
Clock Input Low Voltage	V_{ILC}	V_{SS} − 1		V_{SS} + 0.8	V	
Clock Input High Voltage	V_{IHC}	9.0		V_{DD} + 1	V	
Input Low Voltage	V_{IL}	V_{SS} − 1		V_{SS} + 0.8	V	
Input High Voltage	V_{IH}	3.0		V_{CC} + 1	V	
Output Low Voltage	V_{OL}			0.45	V	I_{OL} = 1.9 mA on all outputs
Output High Voltage	V_{OH}	3.7 3.5			V V	I_{OH} = −150 μA ② I_{OH} = −1.0 mA
Avg. Power Supply Current (V_{DD})	$I_{DD(AV)}$		55	75	mA	t_{CY} min

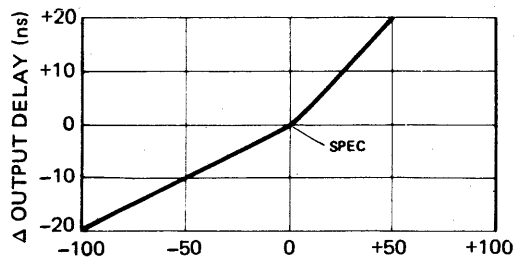
AC CHARACTERISTICS

T_a = −10°C to 70°C; V_{DD} = +12V ± 5%; V_{CC} = +5V ± 5%; V_{BB} = −5V ± 5%; V_{SS} = 0V, unless otherwise specified

PARAMETER	SYMBOL	LIMITS			UNIT	TEST CONDITIONS
		MIN	TYP	MAX		
Clock Period	t_{CY} ③	0.48		2.0	μs	
Clock Rise and Fall Time	t_r, t_f	0		50	ns	
φ1 Pulse Width	$t_{\phi1}$	60			ns	
φ2 Pulse Width	$t_{\phi2}$	220			ns	
Delay φ1 to φ2	t_{D1}	0			ns	
Delay φ2 to φ1	t_{D2}	70			ns	
Delay φ1 to φ2 Leading Edges	t_{D3}	80			ns	
Address Output Delay From φ2	t_{DA} ②			200	ns	C_L = 100 pf
Data Output Delay From φ2	t_{DD} ②			220	ns	
Signal Output Delay From φ1, or φ2 (SYNC, $\overline{WR}$, WAIT, HLDA)	t_{DC} ②			120	ns	C_L = 50 pf
DBIN Delay From φ2	t_{DF} ②	25		140	ns	
Delay for Input Bus to Enter Input Mode	t_{DI} ①			t_{DF}	ns	
Data Setup Time During φ1 and DBIN	t_{DS1}	30			ns	
	t_{DS2}	⑤				
Data Hold Time From φ2 During DBIN	t_{DH} ①	50			ns	
INTE Output Delay From φ2	t_{IE} ②			200	ns	C_L = 50 pf
READY Setup Time During φ2	t_{RS}	120			ns	
READY Setup Time to φ1 High	$t_{RS\phi1}$	240			ns	
HOLD Setup Time to φ2	t_{HS}	140			ns	
INT Setup Time During φ2 (for all modes)	t_{IS}	120			ns	
Hold Time From φ2 (READY, INT, HOLD)	t_H	0			ns	
Delay to Float During Hold (Address and Data Bus)	t_{FD}			120	ns	
Address Stable Prior to $\overline{WR}$	t_{AW} ②	⑥			ns	C_L = 100 pf: Address, Data C_L = 50 pf: $\overline{WR}$, HLDA, DBIN
Output Data Stable Prior to $\overline{WR}$	t_{DW} ②	⑦			ns	
Output Data Stable From $\overline{WR}$	t_{WD} ②	⑧			ns	
Address Stable From $\overline{WR}$	t_{WA} ②	⑧			ns	
HLDA to Float Delay	t_{HF} ②	⑨			ns	
$\overline{WR}$ to Float Delay	t_{WF} ②	⑩			ns	
Address Hold Time After DBIN During HLDA	t_{AH} ②	-20			ns	



Notes: ① Data input should be enabled with DBIN status. No bus conflict can then occur and data hold time is assured. t_{DH} = 50 ns or t_{DF}, whichever is less.

② Load Circuit

③ Actual $t_{CY} = t_{D3} + t_{r\phi2} + t_{\phi2} + t_{f\phi2} + t_{D2} + t_{r\phi1} > t_{CY}$ Min.

TYPICAL Δ OUTPUT DELAY VS. Δ CAPACITANCE

④ The following are relevant when interfacing the μPD8080A to devices having V_{IH} = 3.3V.

a. Maximum output rise time from 0.8V to 3.3V = 100 ns at C_L = SPEC.

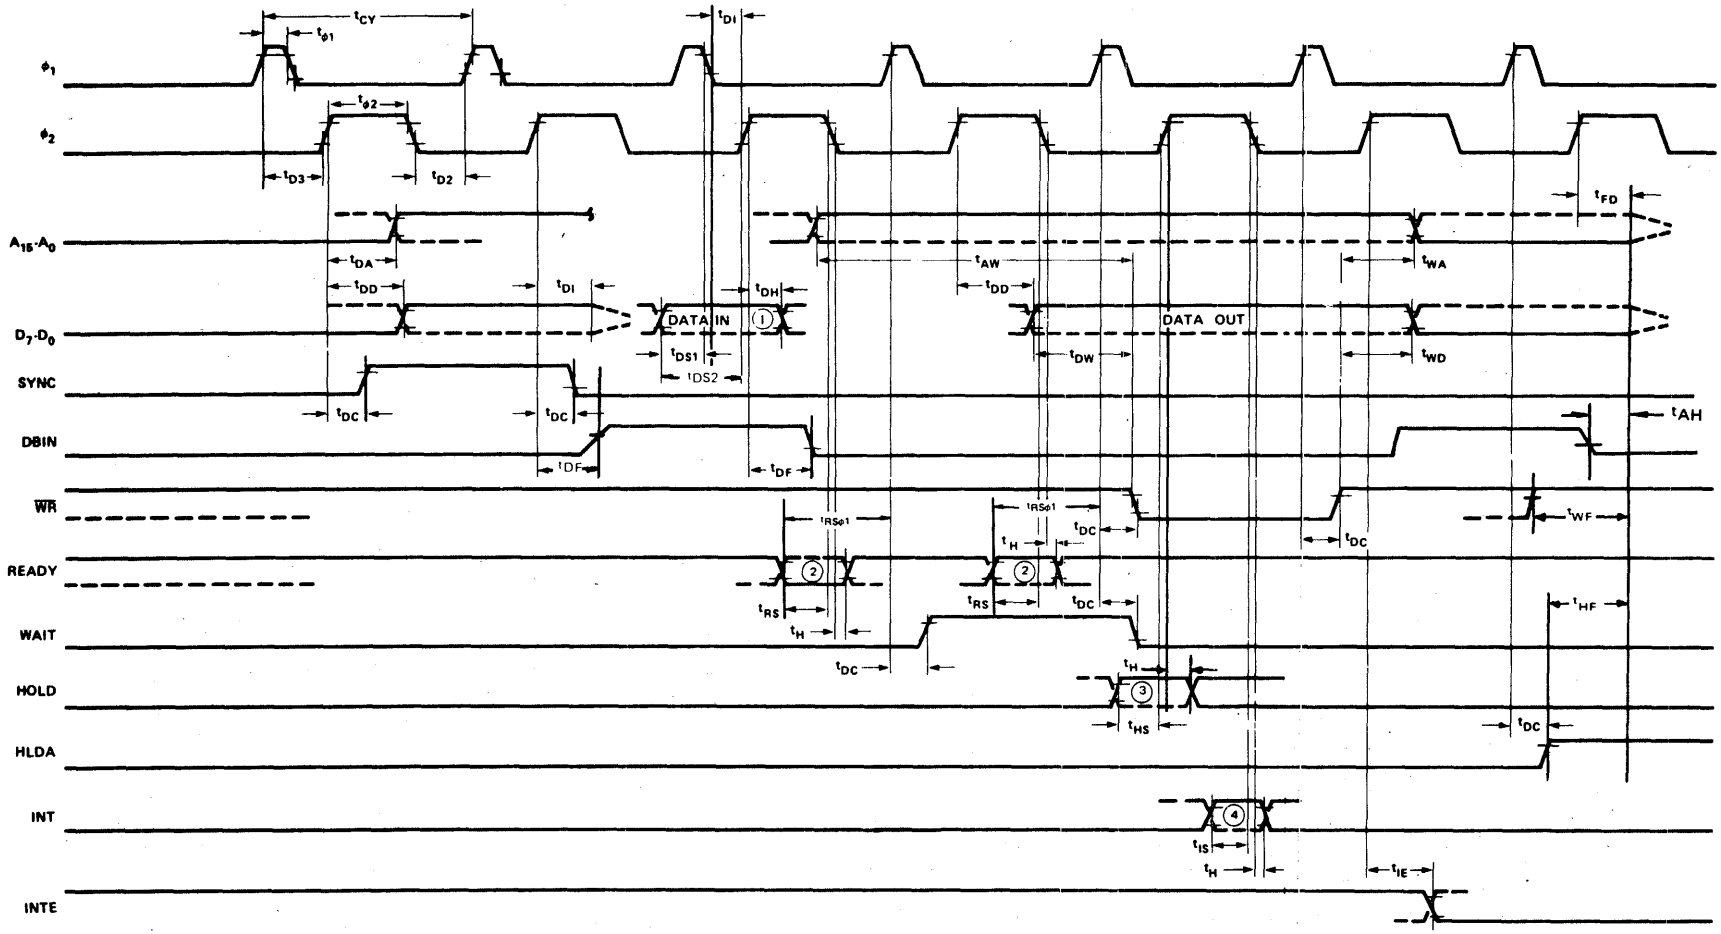
b. Output delay when measured to 3.0V = SPEC + 60 ns at C_L = SPEC.

c. If $C_L \neq$ SPEC, add 0.6 ns/pF if $C_L > C_{SPEC}$, subtract 0.3 ns/pF (from modified delay) if $C_L < C_{SPEC}$.

⑤ No restrictions.

⑥ $t_{AW} = 2\ t_{CY} - t_{D3} - t_{r\phi2} - 140$

⑦ $t_{DW} = t_{CY} - t_{D3} - t_{r\phi2} - 170$



⑧ If not HLDA, $t_{WD} = t_{WA} = t_{D3} + t_{r\phi2} + 10$ ns. If HLDA, $t_{WD} = t_{WA} = t_{WF}$.

⑨ $t_{HF} = t_{D3} + t_{r\phi2} - 50$ ns.

⑩ $t_{WF} = t_{D3} + t_{r\phi2} - 10$ ns.

©IC MASTER 1978

TIMING WAVEFORMS ⑤ ⑥

① Data in must be stable for this period during DBIN T_3. t_{DS1} must be satisfied.

② Ready signal must be stable for this period during T_2. (Must be externally synchronized.)

③ Hold signal must be stable for this period during T_2 when entering hold mode, and during T_3, T_4 and T_5 when in hold mode. (External synchronization is not required.)

④ Interrupt signal must be stable during this period of the last clock cycle of any instruction in order to be recognized on the following instruction. (External synchronization is not required.)

⑤ This timing diagram shows timing relationships only; it does not represent any specific machine cycle.

⑥ Timing measurements are made at the following reference voltages: CLOCK "1" = 8.0V, "0" = 1.0V; INPUTS "1" = 3.0V; "0" = 0.8V; OUTPUTS "1" = 2.0V, "0" = 0.8V.

NOTES:

[1] Operand Symbols used
A = 8-bit address or expression
s = source register
d = destination register
PSW = Processor Status Word
SP = Stack Pointer
D8 = 8-bit data quantity, expression, or constant, always B_2 of instruction
D16 = 16-bit data quantity, expression, or constant, always B_3B_2 of instruction
ADDR = 16-bit Memory address expression

[2] ddd or sss – 000 B – 001 C – 010 D – 011 E – 100 H – 101 L – 110 Memory – 111 A.

[3] Two possible cycle times (5/11) indicate instruction cycles dependent on condition flags.

[4] • = flag affected
= flag not affected
0 = flag reset
1 = flag set

©IC MASTER 1978

INSTRUCTION SET

The instruction set includes arithmetic and logical operators with direct, register, indirect, and immediate addressing modes. These instructions operate exactly like the μPD8080AF except as noted.

In addition to the four testable flags, the μPD8080A has two more flags (ACY, SUB) that are not directly testable. They are used for multiple precision arithmetic operations, particularly with the DAA instruction. The Auxiliary Carry flag is set if the last instruction resulted in a carry or a borrow from bit 3 into bit 4; otherwise it is reset. The Subtract flag is set if the last instruction resulted in a subtract operation being performed; it is reset if an add operation was performed. Also, arithmetic flags are not affected by logical instructions.

DATA AND INSTRUCTION FORMATS

Data in the μPD8080A is stored as 8-bit binary integers. All data/instruction transfers to the system data bus are in the following format:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0

MSB DATA WORD LSB

Instructions are one, two, or three bytes long. Multiple byte instructions must be stored in successive locations of program memory. The address of the first byte is used as the address of the instruction.

		TYPICAL INSTRUCTIONS
One Byte Instructions		
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	Register to register, memory reference, arithmetic or logical, rotate, return, push, pop, enable, or disable interrupt instructions
Two Byte Instructions		
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	Immediate mode or I/O instructions
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OPERAND	
Three Byte Instructions		Jump, call or direct load and store instructions
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	OP CODE	
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	LOW ADDRESS OR OPERAND 1	
D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0	HIGH ADDRESS OR OPERAND 2	

INSTRUCTION CYCLE TIMES

One to five machine cycles ($M_1 - M_5$) are required to execute an instruction. Each machine cycle involves the transfer of an instruction or data byte into the processor or a transfer of a data byte out of the processor (the sole exception being the double add instruction). The first one, two or three machine cycles obtain the instruction from the memory or an interrupting I/O controller. The remaining cycles are used to execute the instruction. Each machine cycle requires from three to five clock times ($T_1 - T_5$). During ϕ_1 SYNC of each machine cycle, a status word that identifies the type of machine cycle is available on the data bus.

Execution times and machine cycles used for each type of instruction are shown below.

INSTRUCTION	MACHINE CYCLES EXECUTED	CLOCK TIMES (MIN/MAX)
RST X and PUSH RP	PCR5 (1) SPW3 (5) SPW3 (5)	11
All CALL Instructions	PCR5 (1) PCR3 (2) PCR3 (2) SPW3 (5) SPW3 (5)	11/17

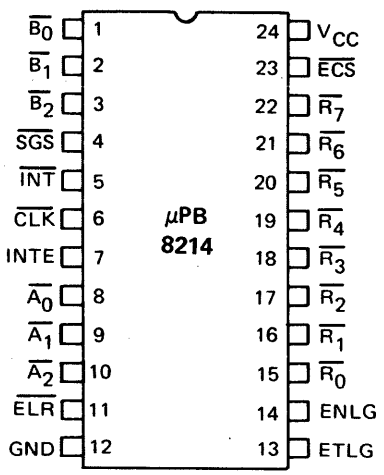
PRIORITY INTERRUPT CONTROLLER

DESCRIPTION

The μPB8214 is an eight-level priority interrupt controller. Designed to simplify interrupt driven microcomputer systems, the μPB8214 requires a single +5V power supply and is packaged in a 24 pin plastic Dual-in-line package.



The μPB8214 accepts up to eight interrupts, determines which has the highest priority and then compares that priority with a software created current status register. If the incoming request is of a higher priority than the interrupt currently being serviced, an interrupt request to the processor is generated. Vector information that identifies the interrupting device is also generated.

The interrupt structure of the microcomputer system can be expanded beyond eight interrupt levels by cascading μPB8214s. The μPB8214's interrupt and vector information outputs are open collector and control signals are provided to simplify expansion of the interrupt structure.

FEATURES

- Eight Priority Levels
- Current Status Register and Priority Comparator
- Easily Expanded Interrupt Structure
- Single +5 Volt Supply

PIN CONFIGURATION

BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

General

The μPB8214 is an LSI device designed to simplify the circuitry required to implement an interrupt driven microcomputer system. Up to eight interrupting devices can be connected to a μPB8214, which will assign priority to incoming interrupt requests and accept the highest. It will also compare the priority of the highest incoming request with the priority of the interrupt being serviced. If the serviced interrupt has a higher priority, the incoming request will not be accepted.

A system with more than eight interrupting devices can be implemented by interconnecting additional μPB8214s. In order to facilitate this expansion, control signals are provided for cascading the controllers so that there is a priority established among the controllers. In addition, the interrupt and vector information outputs are open collector.

Priority Encoder and Request Latch

The priority encoder portion of the μPB8214 accepts up to eight active low interrupt requests ($\overline{R_0}$–$\overline{R_7}$). The circuit assigns priority to the incoming requests, with $\overline{R_7}$ having the highest priority and $\overline{R_0}$ the lowest. If two or more requests occur simultaneously, the μPB8214 accepts the one having the highest priority. Once an incoming interrupt request is accepted, it is stored by the request latch and a three-bit code is output. As shown in the following table, the outputs, ($\overline{A_0}$–$\overline{A_2}$) are the complement of the request level (modulo 8) and directly correspond to the bit pattern required to generate the one byte RESTART (RST) instructions recognized by an 8080A. Simultaneously with the $\overline{A_0}$–$\overline{A_2}$ outputs, a system interrupt request ($\overline{INT}$) is output by the μPB8214. It should be noted that incoming interrupt requests that are *not* accepted are not latched and must remain as an input to the μPB8214 in order to be serviced.

FUNCTIONAL DESCRIPTION (CONT.)

RESTART GENERATION TABLE

PRIORITY REQUEST		RST	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
			1	1	$\overline{A_2}$	$\overline{A_1}$	$\overline{A_0}$	1	1	1
LOWEST	$\overline{R_0}$	7	1	1	1	1	1	1	1	1
	$\overline{R_1}$	6	1	1	1	1	0	1	1	1
	$\overline{R_2}$	5	1	1	1	0	1	1	1	1
	$\overline{R_3}$	4	1	1	1	0	0	1	1	1
	$\overline{R_4}$	3	1	1	0	1	1	1	1	1
	$\overline{R_5}$	2	1	1	0	1	0	1	1	1
	$\overline{R_6}$	1	1	1	0	0	1	1	1	1
HIGHEST	$\overline{R_7}$	0*	1	1	0	0	0	1	1	1

*CAUTION: RST 0 will vector the program counter to location 0 (zero) and invoke the same routine as the "RESET" input to 8080A.

Current Status Register

The current status register is designed to prevent an incoming interrupt request from overriding the servicing of an interrupt with higher priority. Via software, the priority level of the interrupt being serviced by the microprocessor is written into the current status register on $\overline{B_0}$–$\overline{B_2}$. The bit pattern written should be the complement of the interrupt level.

The interrupt level currently being serviced is written into the current status register by driving $\overline{ECS}$ (Enable Current Status) low. The μPB8214 will only accept interrupts with a higher priority than the value contained by the current status register. Note that the programmer is free to use the current status register for other than as above. Other levels may be written into it. The comparison may be completely disabled by driving $\overline{SGS}$ (Status Group Select) low when $\overline{ECS}$ is driven low. This will cause the μPB8214 to accept incoming interrupts only on the basis of their priority to each other.

Priority Comparator

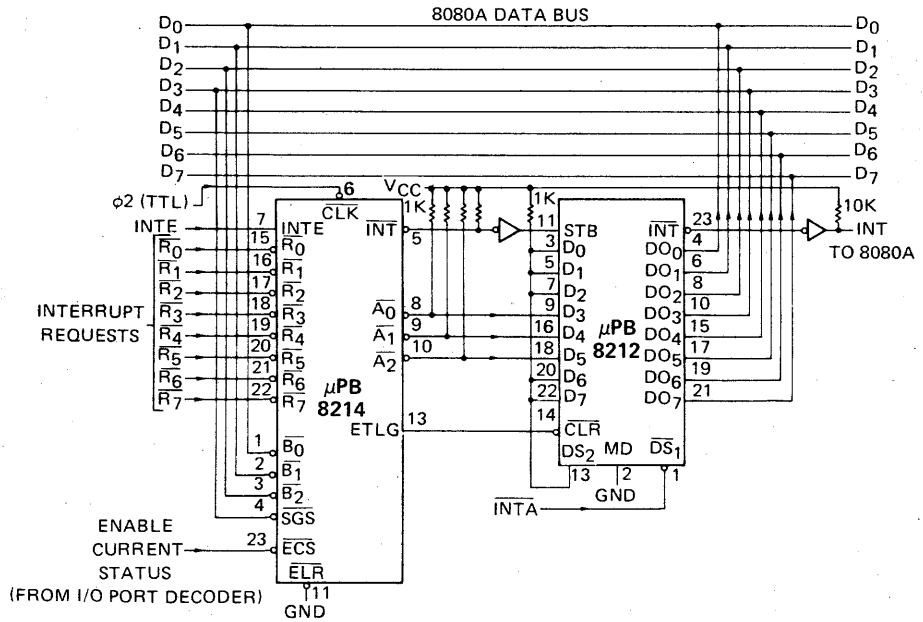
The priority comparator circuitry compares the level of the interrupt accepted by the priority encoder and request latch with the contents of the current status register. If the incoming request has a priority level higher than that of the current status register, the $\overline{INT}$ output is enabled. Note that this comparison can be disabled by loading the current status register with $\overline{SGS}$=0.

Expansion Control Signals

A microcomputer design may often require more than eight different interrupts. The μPB8214 is designed so that interrupt system expansion is easily performed via the use of three signals: ETLG (Enable This Level Group); ENLG (Enable Next Level Group); and $\overline{ELR}$ (Enable Level Read). A high input to ETLG indicates that the μPB8214 may accept an interrupt. In a typical system, the ENLG output from one μPB8214 is connected to the ETLG input of another μPB8214, etc. The ETLG of the μPB8214 with the highest priority is tied high. This configuration sets up priority among the cascaded μPB8214's. The ENLG output will be high for any device that does not have an interrupt pending, thereby allowing a device with lower priority to accept interrupts. The $\overline{ELR}$ input is basically a chip enable and allows hardware or software to selectively disable/enable individual μPB8214's. A low on the $\overline{ELR}$ input enables the device.

©IC MASTER 1978

FUNCTIONAL DESCRIPTION (CONT.)



Interrupt Control Circuitry

The μPB8214 contains two flip-flops and several gates which determine whether an accepted interrupt request to the μPB8214 will generate a system interrupt to the 8080A. A condition gate drives the D input of the interrupt flip-flop whenever an interrupt request has been completely accepted. This requires that: the ETLG (Enable This Level Group) and INTE (Interrupt Enable) inputs to the μPB8214 are high; the $\overline{ELR}$ input is low; the incoming request must be of a higher priority than the contents of the current status register; and the μPB8214 must have been enabled to accept interrupt requests by the clearing of the interrupt disable flip-flop.

Once the condition gate drives the D input of the interrupt flip-flop high, a system interrupt ($\overline{INT}$) to the 8080A is generated on the next rising edge of the $\overline{CLK}$ input to the μPB8214. This $\overline{CLK}$ input is typically connected to the $\phi 2$ (TTL) output of an 8224 so that 8080A set-up time specifications are met. When $\overline{INT}$ is generated, it sets the interrupt disable flip-flop so that no additional system interrupts will be generated until it is reset. It is reset by driving $\overline{ECS}$ (Enable Current Status) low, thereby writing into the current status register.

It should be noted that the open collector $\overline{INT}$ output from the μPB8214 is active for only one clock period and thus must be externally latched for inputting to the 8080A. Also, because the $\overline{INT}$ output is open collector, when μPB8214's are cascaded, an $\overline{INT}$ output from any one will set all of the interrupt disable flip-flops in the array. Each μPB8214's interrupt disable flip-flop must then be cleared individually in order to generate subsequent system interrupts.

TYPICAL μPB8214 CIRCUITRY

ABSOLUTE MAXIMUM RATINGS*

Operating Temperature	0°C to +70°C
Storage Temperature	−65°C to +125°C
All Output and Supply Voltages	−0.5 to +7 Volts
All Input Voltages	−1.0 to +5.5 Volts
Output Currents	100 mA

COMMENT: Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

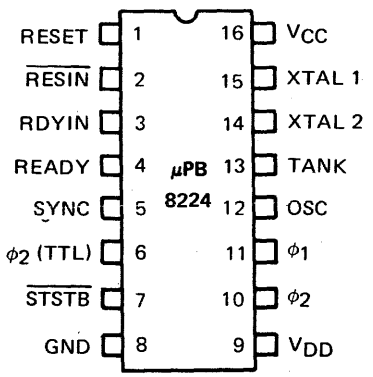
CLOCK GENERATOR AND DRIVER FOR 8080A PROCESSORS

DESCRIPTION

The μPB8224 is a single chip clock generator and driver for 8080A processors. The clock frequency is determined by a user specified crystal and is capable of meeting the timing requirements of the entire 8080A family of processors. MOS and TTL level clock outputs are generated.



Additional logic circuitry of the μPB8224 provides signals for power-up reset, an advance status strobe and properly synchronizes the ready signal to the processor. This greatly reduces the number of chips needed for 8080A systems.

The μPB8224 is fabricated using NEC's Schottky bipolar process.

FEATURES

- Crystal Controlled Clocks
- Oscillator Output for External Timing
- MOS Level Clocks for 8080A Processor
- TTL Level Clock for DMA Activities
- Power-up Reset for 8080A Processor
- Ready Synchronization
- Advanced Status Strobe
- Reduces System Package Count
- Available in 16-pin Cerdip and Plastic Packages

Clock Generator

The clock generator circuitry consists of a crystal controlled oscillator and a divide-by-nine counter. The crystal frequency is a function of the 8080A processor speed and is basically nine times the processor frequency, i.e.:

$$\text{Crystal frequency} = \frac{9}{t_{CY}}$$

where t_{CY} is the 8080A processor clock period.

A series resonant fundamental mode crystal is normally used and is connected across input pins XTAL1 and XTAL2. If an overtone mode crystal is used, an additional LC network, AC coupled to ground, must be connected to the TANK input of the μPB8224 as shown in the following figure.

The formula for the LC network is:

$$LC = \left(\frac{1}{2\pi F}\right)^2$$

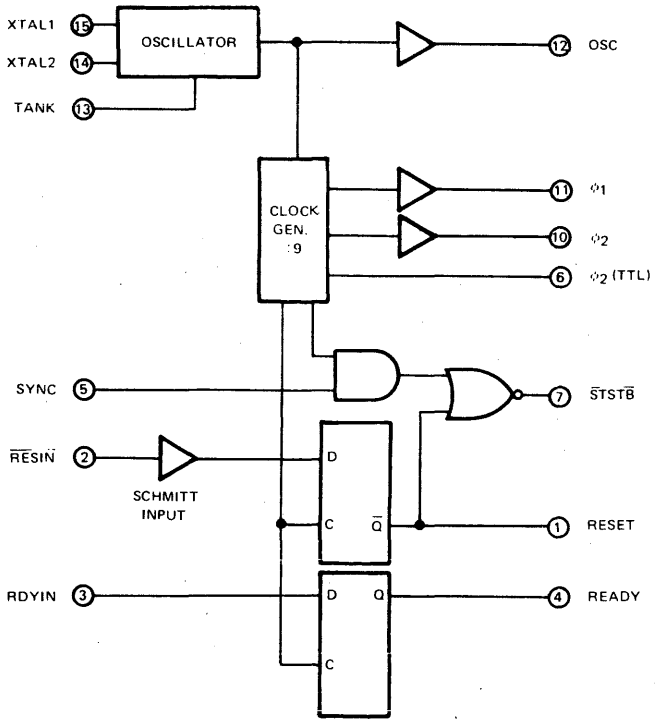
where F is the desired frequency of oscillation.

The output of the oscillator is input to the divide-by-nine counter. It is also buffered and brought out on the OSC pin, allowing this stable, crystal controlled source to be used for derivation of other system timing signals. The divide-by-nine counter generates the two non-overlapping processor clocks, ϕ_1 and ϕ_2, which are buffered and at MOS levels, a TTL level ϕ_2 and internal timing signals.

The ϕ_1 and ϕ_2 high level outputs are generated in a 2-5-2 digital pattern, with ϕ_1 being high for two oscillator periods, ϕ_2 being high for five oscillator periods, and then neither being high for two oscillator periods. The TTL level ϕ_2,ϕ_2 (TTL), is normally used for DMA activities by gating the external device onto the 8080A bus once a Hold Acknowledge (HLDA) has been issued.

Additional Logic

In addition to the clock generator circuitry, the μPB8224 contains additional logic to aid the system designer in the proper timing of several interface signals.



The $\overline{\text{STSTB}}$ signal indicates, at the earliest possible moment, when the status signals output from the 8080A processor are stable on the data bus. $\overline{\text{STSTB}}$ is designed to connect directly to the μPB8228 System Controller and automatically resets the μPB8228 during power-on Reset.

The $\overline{\text{RESIN}}$ input to the μPB8224 is used to automatically generate a RESET signal to the 8080A during power initialization. The slow rise of the power supply voltage in an external RC network is sensed by an internal Schmitt Trigger. The output of the Schmitt Trigger is gated to generate an 8080A compatible RESET. An active low manual switch may also be attached to the RC circuit for manual system reset.

The RDYIN input to the μPB8224 accepts an asynchronous "wait request" and generates a READY output to the 8080A that is fully synchronized to meet the 8080A timing requirements.

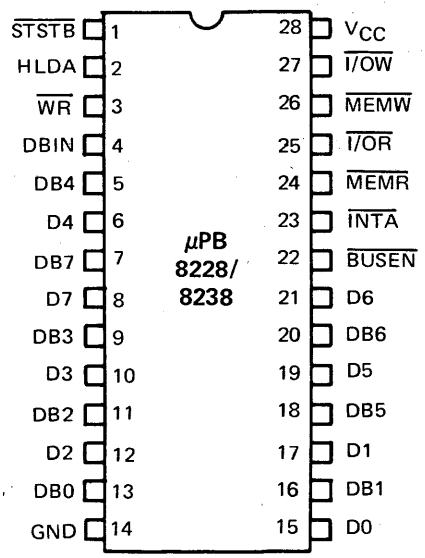
8080A SYSTEM CONTROLLER AND BUS DRIVER

DESCRIPTION

The μPB8228/8238D is a single chip controller and bus driver for 8080A based systems. All the required interface signals necessary to connect RAM, ROM and I/O components to a μPD8080A are generated.

The μPB8228/8238D provides a bi-directional three-state bus driver for high TTL fan-out and isolation of the processor data bus from the system data bus for increased noise immunity.



The system controller portion of the μPB8228/8238D consists of a status latch for definition of processor machine cycles and a gating array to decode this information for direct interface to system components. The controller can enable gating of a multi-byte interrupt onto the data bus or can automatically insert a RESTART 7 onto the data bus without any additional components.

Two devices are provided. The μPB8228D for small systems without tight write timing constraints and the μPB8238D for larger systems.

FEATURES

- System Controller for 8080A Systems
- Bi-Directional Data Bus for Processor Isolation
- 3.60V Output High Voltage for Direct Interface to 8080A Processor
- Three State Outputs on System Data Bus
- Enables Use of Multi-Byte Interrupt Instructions
- Generates RST 7 Interrupt Instruction
- μPB8228 for Small Memory Systems
- μPB8238 for Large Memory Systems
- Reduces System Package Count
- Schottky Bipolar Technology

PIN CONFIGURATION

NC: No Connection

FUNCTIONAL DESCRIPTION

Bi-Directional Bus Driver

The eight bit, bi-directional bus driver provides buffering between the processor data bus and the system data bus. On the processor side, the μPB8228/8238D exceeds the minimum input voltage requirements (3.0V) of the μPD8080A. On the system side, the driver is capable of adequate drive current (10 mA) for connection of a large number of memory and I/O devices to the bus. Signal flow in the bus driver is controlled by the gating array and its outputs can be forced into a high impedance state by use of the $\overline{\text{BUSEN}}$ input.

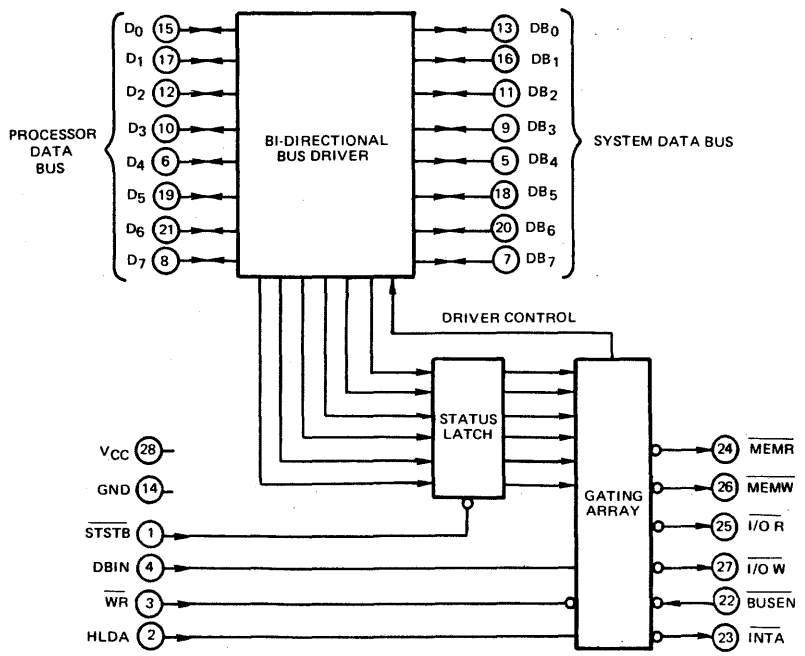
Status Latch

The Status Latch in the μPB8228/8238D stores the status information placed on the data bus by the 8080A at the beginning of each machine cycle. The information is latched when $\overline{\text{STSTB}}$ goes low and is then decoded by the gating array for the generation of control signals.

Gating Array

The Gating Array generates "active low" control signals for direct interfacing to system components by gating the contents of the status latch with control signals from the 8080A.

$\overline{\text{MEM/R}}$, $\overline{\text{I/OR}}$ and $\overline{\text{INTA}}$ are generated by gating the DBIN signal from the processor with the contents of the status latch. $\overline{\text{I/OR}}$ is used to enable an I/O input onto the system data bus. $\overline{\text{MEM/R}}$ is used to enable a memory input.



$\overline{\text{INTA}}$ is normally used to gate an interrupt instruction onto the system data bus. When used with the μPD8080A processor, the μPB8228/8238D will decode an interrupt acknowledge status word during all three machine cycles for a multi-byte interrupt instruction. For 8080A type processors that do not generate an interrupt acknowledge status word during the second and third machine cycles of a multi-byte interrupt instruction, the μPB8228/8238 will internally generate an $\overline{\text{INTA}}$ pulse for those machine cycles.

The μPB8228/8238D also provides the designer the ability to place a single interrupt instruction onto the bus without adding additional components. By connecting the +12 volt supply to the $\overline{\text{INTA}}$ output (pin 23) of the μPB8228/8238D through a 1K ohm series resistor, RESTART 7 will be gated onto the processor data bus when DBIN is active during an interrupt acknowledge machine cycle.

$\overline{\text{MEM/W}}$ and $\overline{\text{I/OW}}$ are generated by gating the $\overline{\text{WR}}$ signal from the processor with the contents of the status latch. $\overline{\text{I/OW}}$ indicates that an output port write is about to occur. $\overline{\text{MEM/W}}$ indicates that a memory write will occur.

The data bus output buffers and control signal buffers can be asynchronously forced into a high impedance state by placing a high on the $\overline{\text{BUSEN}}$ pin of the μPB8228/8238. Normal operation is performed with $\overline{\text{BUSEN}}$ low.

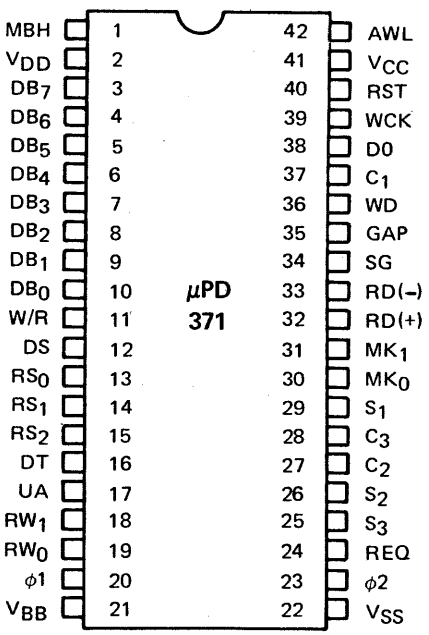
MAGNETIC TAPE CASSETTE/ CARTRIDGE CONTROLLER

DESCRIPTION

The NEC μPD371 is a high performance N-Channel LSI tape cassette/cartridge controller designed to interface between most cassette or cartridge tape drives and most microprocessors or minicomputers.

The μPD371 converts 8-bit parallel data into serial phase encoded data to be written on tape and converts phase encoded data read from tape into 8-bit parallel data, calculates the CRC during write operations, verifies the CRC during read operations, informs the processor program when to send data bytes during write operations and when to read bytes during read operations, converts tape drive status signals into register bit levels which may be read by the processor program and converts software commands into signals which may be understood by the tape drive(s).



The μPD371 read and write data paths are completely separate to allow read-after-write data verification.

The μPD371 places no limitation on the selection of tape speed since the μPD371 maximum data transfer rate is considerably faster than that of the fastest cassette or cartridge drive.

FEATURES

- Compatible with ANSI, ECMA and ISO standard
- Also compatible with most other standards
- Hardware CRC generation and verification
- Read-after-write capability
- High speed file search
- Multiple drive capability
- May read or write on one drive while rewinding or file searching on another
- Maximum Data Transfer rate of 375K bits/sec equivalent to 468 IPS at 800 BPI

PIN IDENTIFICATION①

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
RESET			
40	RST	Reset	A logic one at this pin causes a general reset of the μPD371.
REGISTER SELECT COMMANDS AND DATA BUS			
11	W/R		W/R, DS and $RS_0 - RS_2$ control Data Bus transfers between the μPD371 and the processor as follows: Writing into a μPD371 register: When W/R is a logic one, information the processor places on $DB_0 - DB_7$ is written into the μPD371 WRITE REGISTER selected by $RS_0 - RS_2$. The information is strobed into the register by a logic one at DS. Reading from a μPD371 register: When W/R is a logic zero, information from the μPD371 READ REGISTER selected by $RS_0 - RS_2$ is placed on $DB_0 - DB_7$ to be read by the processor. The information remains on $DB_0 - DB_7$ as long as DS is a logic one.
12	DS		
13 – 15	$RS_0 - RS_2$		
3 – 10	$DB_0 - DB_7$	Data Bus	
INTERRUPT REQUEST			
24	REQ		The μPD371 may be operated with either interrupt or polling techniques. If the interrupt technique is chosen, REQ should be connected to the interrupt request input of the processor. There are three sources of interrupt: READ BUFFER FULL, WRITE BUFFER EMPTY and GAP DETECTION.
TIMING			The user must provide four timing signals to the μPD371 — one for write operations and three for read operations. Each is defined in terms of T, where T is the period between successive data transitions in the phase encoded data written onto or read from tape.
39	WCK		WCK determines the WRITE DATA (WD, pin 36) transfer rate. WCK should have a period of 0.5T. DT is a pulse provided by the μPD371 to be used in the generation of the three read timing signals — SG, DO, and GAP. DT occurs at each data transition in the data read from tape. The internal read data sample gate is closed following each data transition and is reopened by a positive transition at SG 0.75T μsec after each DT pulse. A positive transition should be made at DO whenever a DT pulse stream ceases for a period of 1.5T μsec. A positive transition should be made at GAP whenever a DT pulse stream ceases for a period of 4T μsec. $\phi 1$ and $\phi 2$ are MOS level (12V) clock pulses. The timing of $\phi 1$ and $\phi 2$ is shown in the Timing Diagram.
16	DT		
34	SG		
38	DO		
35	GAP		
20	$\phi 1$		
23	$\phi 2$		
WRITE DATA			
36	WD		Phase encoded data to be written on tape leaves the μPD371 at pin 36.
TAPE DRIVE COMMAND AND STATUS			
37	C_1		C_1, C_2 and C_3 are general purpose tape drive commands. C_1, C_2 and C_3 are set and reset by the software manipulation of bits 5, 6 and 7, respectively, in Write Register 3. Since C_1, C_2 and C_3 are defined by software, they may be configured for any purpose. Typical uses for C_1, C_2 and C_3 are WRITE ENABLE, FORWARD and REVERSE.
27	C_2		
28	C_3		
29	S_1		S_1, S_2 and S_3 are general purpose tape drive status inputs. Their logic levels are indicated by bits 3, 4 and 7 of Read Register 1, respectively. Typical tape drive status signals are WRITE PERMIT, CASSETTE IN PLACE and SIDE. The μPD371 can adapt to any tape drive status signal set with a slight change in software.
26	S_2		
25	S_3		
DUAL TAPE DRIVE SYSTEM COMMAND AND STATUS			
17	UA	Unit Address	Selects Drive 0 when low and Drive 1 when high.
19	RW_0	Rewind 0	Rewind Command for Drive 0.
18	RW_1	Rewind 1	Rewind Command for Drive 1.
30	MK_0	Marker 0	EOT/BOT status from Drive 0.
31	MK_1	Marker 1	EOT/BOT status from Drive 1.
READ DATA			
32	RD(+)	Read Data (+)	A positive pulse from the tape drive at each positive transition in the read data.
33	RD(–)	Read Data (–)	A positive pulse from the tape drive at each negative transition in the read data.
MISCELLANEOUS			
1	MBH		MBH must be tied to the V_{CC} (+5V) supply.
42	AWL		AWL is a logic low output under all normal operating conditions of the μPD371.
POWER SUPPLY VOLTAGES			
2	V_{DD}		+12V
41	V_{CC}		+5V
22	V_{SS}		Ground
21	V_{BB}		–5V

ADDRESSABLE INTERNAL REGISTERS

From the point of view of the processor program, the μPD371 makes the tape drive (or multiple drive system) appear as ten addressable registers. The program controls the drive(s) and transmits data to be written on tape by manipulating bits in the six μPD371 Write Registers. The program senses the status of the drive(s) and reads data stored on tape by reading bits from the four μPD371 Read Registers.

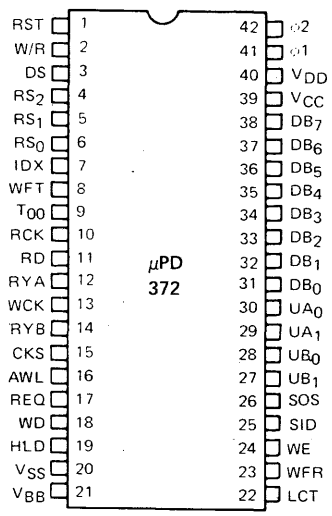
FLOPPY DISK CONTROLLER

DESCRIPTION

The μPD372D is a single LSI floppy disk controller chip which contains the circuitry to read, write, track seek, load and unload the head, generate and detect CRC characters, and perform all other floppy disk operations. It is completely compatible with the IBM, Minifloppy*TM, hard sector, and other formats and controls up to 4 floppy disk drives. The μPD372D may be interfaced directly to a host processor; or to a controller processor first, which in turn is interfaced to the host. These processors do not necessarily have to be of the 8080A type.

Data transfers to and from the μPD372D are done through addressable internal registers. These internal regsiters allow a large variety of system architectures to be configured; they provide status information on the drive, as well as perform data transfers between the drive and the processor.

The μPD372D issues interrupts to the processor upon detection of an address mark and then when each subsequent data byte is available during either reading or writing. An 8-bit bi-directional data bus and 5 register select lines provide access to the 9 internal registers' contents. An internal interval timer is provided which facilitates performing such drive timing functions as: stepping rate, head settling time, track settling time, etc.



*TMShugart Associates.

FEATURES

- Compatible with IBM 3740 format
- Also compatible with other formats including Minifloppy and hard sector
- Controls up to four floppy disk drives
- Can perform overlap seeks
- Input and output TTL compatible (except for $\phi 1$ and $\phi 2$)
- Interfaces to most microprocessors including 8080A
- Standard power supplies (+12V, +5V and –5V)
- Controls most floppy disk drives including:

CALCOMP 140, 142	ORBIS 74, 76/77
CDC BR803	PERSCI 70, 75
INNOVEX 210, 410	REMEX RFS 7400
PERTEC FD400	SHUGART SA400 (Minifloppy)
POTTER DD4740	WANGCO 82 (Minifloppy)
SHUGART SA900, SA800	GSI MDD50 (Minifloppy)
GSI 110

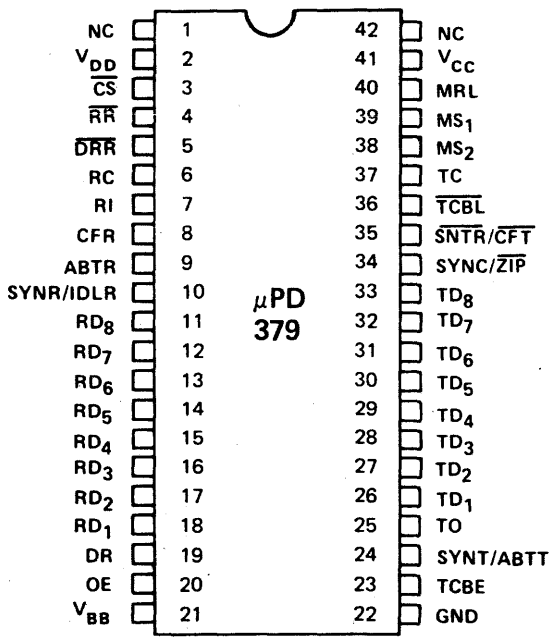
SYNCHRONOUS RECEIVER/TRANSMITTER



DESCRIPTION

The μPD379 Synchronous Receiver/Transmitter is an MOS LSI monolithic circuit that performs all the receiving and transmitting functions associated with Basic and High Level Data Link Control Procedures. This circuit is fabricated using N-channel AL-Gate MOS technology, allowing all inputs and outputs to be directly TTL compatible. The operation mode, baud rate and synchronous character are changeable through the use of external control. The μPD379 is packaged in a 42 pin Dual-in-line ceramic package.

FEATURES

- Suitable for Synchronous Basic and High Level Data Link Control Procedures (BiSync or SDLC)
- Full or Half Duplex Operation
- Fully Double Buffered Transmit and Receive
- Directly TTL Compatible
- Three-State Data Outputs
- Programmable Sync Word
- Detection/Rejection of Flag, Abort and Idle Patterns
- Zero Insertion and Rejection
- Indication of Overrun and Underrun Errors
- 800K Bits/Sec Operating Speed

PIN CONFIGURATION

NC: NO CONNECTION

©IC MASTER 1978

Basic Sync Mode Transmission

The Sync character may be 16 in hexadecimal or it may be set to any other pattern in the Closed Mode. When the mode control register is loaded with MS_1 = high and MS_2 = low, the μPD379 enters the Basic Sync mode from the Closed Mode. The Sync character is continuously transmitted until a transmission data character is loaded. After a data character is loaded, it is serialized and transmitted out from the TO (Transmitter Output) line. If an underrun occurs, Sync character(s) are again transmitted automatically until the next data character is loaded. Transmission data is sent out from LSB (TD_1) first to MSB (TD_8) last on the TO line.

Basic Sync Mode Receive

The RI (Receiver Input) line first searches for Sync characters. Once an 8-bit Sync character has been detected, the following received bits are treated as data characters and outputted on lines $RD_1 - RD_8$ in parallel.

When device operation is started, the receiver section should be first brought into Closed mode or should be reset in order to ensure synchronization.

SDLC Mode Transmission

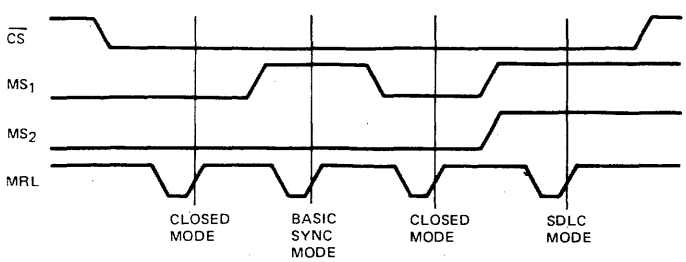
Until a data character is loaded, the Flag pattern (7E in hexadecimal) is automatically transmitted continuously. After a data character is loaded, it is serialized and transmitted out from LSB (TD_1) to MSB (TD_8) on the TO line. In transmitting data characters, a dummy bit 0 is automatically inserted immediately following five (5) successive 1's. This is called Zero-Insertion and is performed in order to maintain synchronization with the receiver and to avoid duplication of Flag pattern in data characters. (Zero-Insertion may be prohibited optionally with the $\overline{ZIP}$ command, if necessary.) If an underrun occurs while data characters are being transmitted, an Abort pattern (FF in hexadecimal) and then a Flag pattern are automatically transmitted. After that, the Flag pattern is again automatically transmitted until the next data character is loaded.

If a low level is placed on the $\overline{CFT}$ (Closing Flag Transmit) line while a data character is being transmitted, a Closing Flag will be transmitted immediately following transmission of the current data character.

SDLC Mode Receive

First, the Flag pattern is searched for on the RI line. Once a Flag pattern is detected, inserted zero's are rejected from all the following characters except Flag, Abort (7 to 14 successive 1's) and Idle (15 successive 1's) patterns, and then deserialized and output on the $RD_1 - RD_8$ lines in parallel.

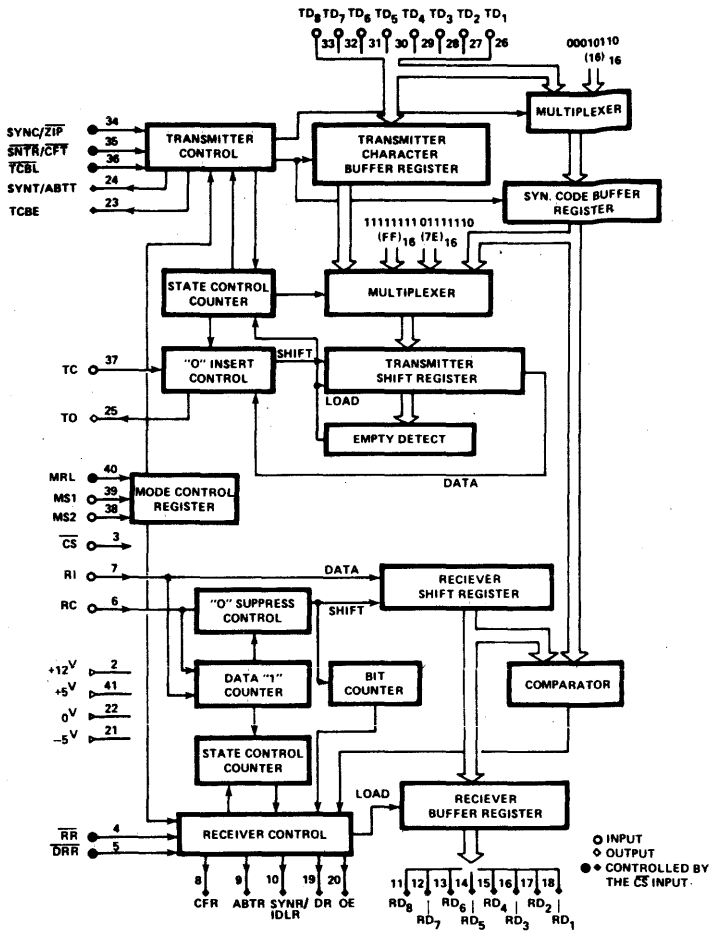
If an overrun occurs, all the following data inputs are neglected and the μPD379 goes back to the first stage to search for the next Flag pattern.



Closed Mode

When there is a change of mode, it must pass through the closed mode. In the closed mode, the following input signals may be used:

$\overline{CS}$, SYNC, $\overline{TCBL}$, MS1, MS2, MRL, $TD_1 - TD_8$



After leaving the closed mode, Sync characters are transmitted synchronously with the rising edge of TC. The receiver operates synchronously with the falling edge of RC, after $\overline{RR}$ = 1.

The following timing diagram shows how mode changes may be accomplished.

PIN IDENTIFICATION

PIN NO.	PIN SYMBOL	FUNCTION: BASIC SYNC MODE	FUNCTION: SDLC MODE
1	NC	No Connection	
2	V_{DD}	+12V Power Supply	
3	$\overline{CS}$	Chip Select – When "1", the following inputs are disabled and the outputs are put into the high impedance state: (Input Disabled) $\overline{RR}$, $\overline{DRR}$, SYNC/$\overline{ZIP}$, $\overline{SNTR}$/$\overline{CFT}$, $\overline{TCBL}$, MRL; (Output-High Impedance) CFR, ABTR, SYNR/IDLR, RD_1 – RD_8, DR, OE, TCBE, CYNT/ABTT	
4	$\overline{RR}$	Receiver Reset – Receiver portion is reset with a "0" and operation is stopped RD_1 – RD_8 ~ – – – "1" CFR, ABTR, SYNR/IDLR, AR, OE – – – – "0"	
5	$\overline{DRR}$	Data Received Reset – Resets DR flag to "0"	
6	RC	Receiver Clock – Receiver clock input. Trailing edge of clock is located in the center of receiver input bits (RI).	
7	RI	Receiver Input – Received data serial input	
8	CFR	(Normally "0")	Closing Flag Received – Goes high whenever a Flag has been received during data reception. Goes low on the rising edge of DR or OE commands
9	ABTR	("0" Constant)	Abort Received – Becomes "1" when 7 – 14 continuous "1"s are received, after receiving the flag. Goes low on the rising edge of DR or OE commands.
10	SYNR / $\overline{IDLR}$	Sync Character Received – Goes high when synchronization has occurred, or whenever the contents of the Sync Character Buffer and the contents of the Receiver Character Buffer coincide. Goes low when DR goes high and the RD_1 – RD_8 outputs are different from the Sync Character.	Idle Pattern Received – Becomes "1" (Idle) when it receives 15 consecutive "1"s. Goes low on the rising edge of DR or OE outputs.
11 – 18	RD_8 – RD_1	Receiver Data Outputs – Received character output terminal (RD_1:LSB RD_8:MSB)	
19	DR	Data Received – Goes high when the received character has been transferred from the Receiver Shift Register to the Receiver Buffer Register	
		DR does not go high for the first Sync Character input. It is reset when DRR is driven low.	DR does not go high for Flag, Abort or Idle Patterns. It is reset when (1) $\overline{DRR}$ = "0", (2) On the rising edge of OE, (3) Seven (7) successive "1"s have been received.
20	OE	Overrun Error – OE = "1" shows that DR was still high when the received character is moved from the receiving shift register to the receiving buffer register	
		OE is reset if DR is low when the received character is transferred from the Receiver Shift Register to the Receiver Buffer Register	It is reset on the rising edge of DR
21	V_{BB}	–5V Power Supply	
22	V_{SS}	Ground	
23	TCBE	Transmitter Character Buffer Register Empty – TCBE = "1" when the transmitter character buffer is empty.	
		TCBE is reset when $\overline{TCBL}$ is driven low	It is reset when: (1) $\overline{TCBL}$ = "0", (2) When $\overline{CFT}$ = "0" in the data transmission mode, (3) One-half bit before ABTT goes high.
24	SYNT / ABTT	SYNC Character Transmit – SYNT = "1" when a synchronous character is being transmitted. It is reset when: (1) $\overline{SNTR}$ = "0", (2) when transmission of data commences	Abort Pattern Transmit – ABTT = "1" when an Abort Pattern is being transmitted
25	TO	Transmitter Output – Transmitter data output. TO = "1" in the closed mode.	
26 – 33	TD_1 – TD_8	Transmitter Data Inputs – Transmitter character input. (TD_1 = LSB, TD_8 = MSB)	
34	SYNC / $\overline{ZIP}$	SYNC Character – In the Closed Mode, the SYNC line is used to select a SYNC character to be loaded into the SYNC Character Buffer. The selected SYNC character is loaded into the buffer on the rising edge of TCBL and is selected as follows: (1) When SYNC = "0", the character placed on the TD_1 – TD_8 inputs is loaded, (2) When SYNC = "1", 16 Hexadecimal is loaded.	Zero Insertion Prohibit – When $\overline{ZIP}$ is driven low, zero-insertion will be prohibited for all subsequent data characters until a Closing Flag or an Abort Pattern is transmitted.
35	$\overline{SNTR}$ / $\overline{CFT}$	SYNC Character Transmit Reset – When $\overline{SNTR}$ is driven low, SYNT is reset to "0".	Closing Flag Transmit – During transmission, $\overline{CFT}$ low causes the following operations to occur: (1) TCBE Output is reset to "0", (2) The Closing Flag will be transmitted after the end of transmission of the current data character.
36	$\overline{TCBL}$	Transmitter Character Buffer Load – (1) In the closed Mode: the SYNC Character Buffer is loaded on the rising edge of $\overline{TCBL}$. If the SYNC input is low, the buffer is loaded with the data on the TD_1 – TD_8 inputs; if SYNC is high, the buffer is loaded with (16) Hex. (2) In the Basic SYNC or SDLC Modes: When $\overline{TCBL}$ is driven low (a) TCBE is reset to "0" and (b) the data character on the TD_1 – TD_8 inputs is loaded into the Transmitter Character Buffer. The loaded character is latched on the rising edge of $\overline{TCBL}$.	
37	TC	Transmitter Clock – Clock input for transmission.	
38	MS_2	Mode Select 2	
39	MS_1	Mode Select 1 Used to select one of three modes. MS_1 MS_2 MODE L L Closed Mode L H Closed Mode H L Basic Synchronous Mode H H SDLC Synchronous Mode In the closed mode TO and RD_1 – RD_8 are high, all other outputs are low.	
40	MRL	Mode Control Register Load – When MRL is low, the operational mode is selected by the current status of MS_1 and MS_2. When MRL goes high, the operational mode is latched based upon the status of MS_1 and MS_2.	
41	V_{CC}	+5V Power Supply	
42	NC	No Connection

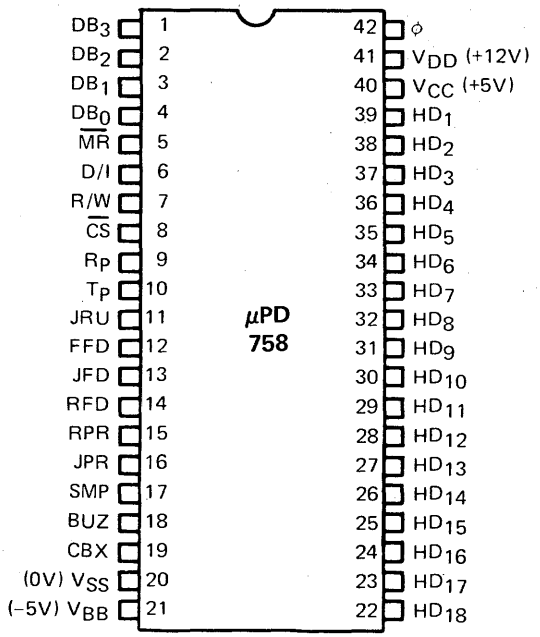
PRINTER CONTROLLER

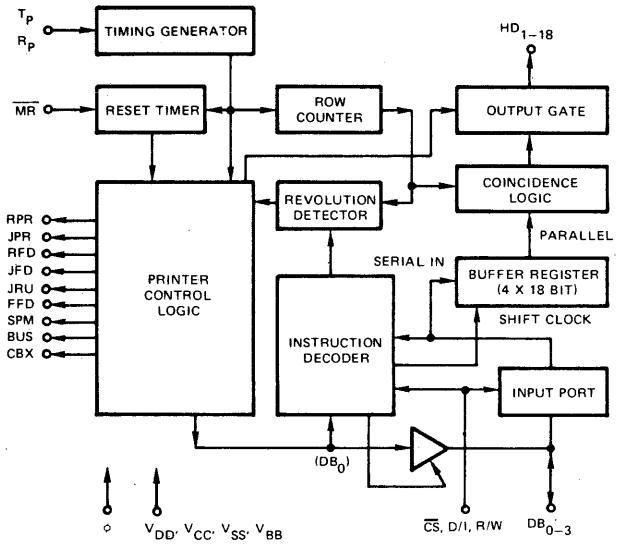
DESCRIPTION



The μPD758 is a digital LSI device designed to control SEIKO 101 Series drum-type impact printers. It can be used with either single or double printer systems. The μPD758, ideally suited for low-cost Electronic Cash Register (ECR) systems, frees the processor from direct control of the printer and simplifies the peripheral circuitry.

Using a few of the possible 18 instructions, the controlling processor need only load the μPD758 with the characters to be printed, and issue the appropriate print instruction. The μPD758 then assumes control of the printer, keeping track of the printer drum position and generating hammer drive signals at the approproate time. The μPD758 also has separate output drives that are under software control. These are typically used to drive the STAMP input to the printer and to provide discrete drives for BUZZER and CASH BOX functions of the ECR system.

FEATURES



- Usable with SEIKO 101 Series Printers (CR101T[d], EP101S) and equivalents
- ECR Printer and Line Feed Control Capability
- 18 Powerful Instructions
- Controls up to 18 columns
- Controls up to 16 characters
- Input/Output TTL Compatible
- N-Ch MOS
- 42 Pin Plastic DIP
- Power Supplies, +12V, +5V and -5V

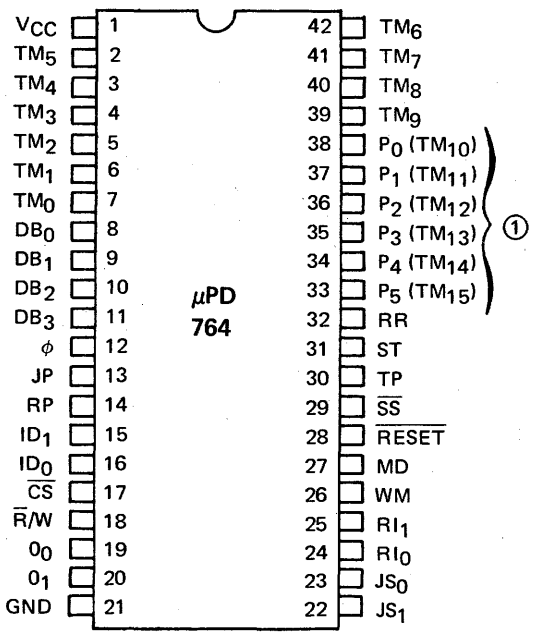
PRINTER CONTROLLER



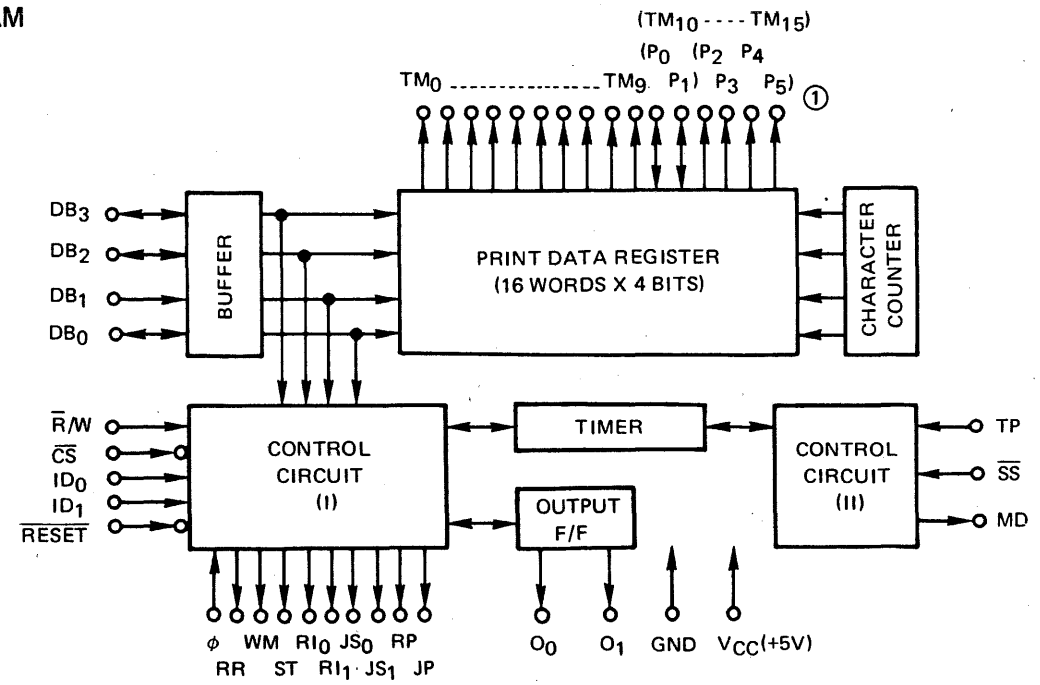
DESCRIPTION

The μPD764 is a digital LSI device designed to control SEIKO CR-330 or M-310 rolling contact printers. The μPD764, which is ideally suited for low-cost Electronic Cash Register (ECR) systems, frees the processor from direct control of the printer and simplifies the peripheral circuitry.

The processor need only load the μPD764 with the characters to be printed and issue the appropriate print command. The μPD764 then assumes control of the printer – positioning the print wheels, initiating the rolling contact print process, feeding paper and feeding ribbon automatically without further processor intervention.

FEATURES

- Compatible with SEIKO CR-330 and M-310 Printers.
- Simple Interface to 4-Bit, 8-Bit and 16-Bit Microprocessors.
- 23 Powerful Instructions.
- 4-Bit Data Bus for Print Data and Instruction Inputs.
- 16 Digit Data Buffer.
- 16 Trigger Magnet Drive Outputs for the M-310 and 10 for the CR-330.
- Single Phase Clock Input. 300, 400 or 500 kHz Selectable.
- Input/Output and Clock TTL Compatible.
- N-Channel MOS.
- Single +5V Power Supply.



Note: ① $P_0 - P_{15}$ for CR-330 Printer
$TM_{10} - TM_{15}$ for M-310 Printer

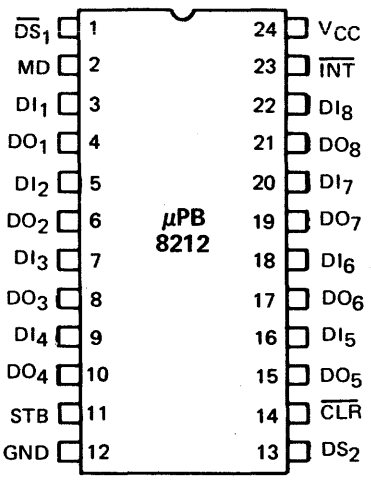
EIGHT-BIT INPUT/OUTPUT PORT

DESCRIPTION



The μPB8212 input/output port consists of an 8-bit latch with three-state output buffers along with control and device selection logic. Also included is a service request flip-flop for the control and generation of interrupts to the microprocessor.

The device is multimode in nature and can be used to implement latches, gated buffers or multiplexers. Thus, all of the principal peripheral and input/output functions of a microcomputer system can be implemented with this device.

FEATURES

- Fully Parallel 8-Bit Data Register and Buffer
- Service Request Flip-Flop for Interrupt Generation
- Low Input Load Current – 0.25 mA Max.
- Three State Outputs
- Outputs Sink 15 mA
- 3.65V Output High Voltage for Direct Interface to 8080A Processor
- Asynchronous Register Clear
- Replaces Buffers, Latches and Multiplexers in Microcomputer Systems
- Reduces System Package Count
- Available in 24-pin Plastic and Cerdip Packages

PIN CONFIGURATION

$\overline{CLR}$	Clear (Active Low)

Rev/1

©IC MASTER 1978

Data Latch

The 8 flip-flops that compose the data latch are of a "D" type design. The output (Q) of the flip-flop follows the data input (D) while the clock input (C) is high. Latching occurs when the clock (C) returns low.

The data latch is cleared by an asynchronous reset input ($\overline{CLR}$).
(Note: Clock (C) Overrides Reset ($\overline{CLR}$).)

Output Buffer

The output of the data latch (Q) are connected to three-state, non-inverting output buffers. These buffers have a common control line (EN); enabling the buffer to transmit the data from the outputs of the data latch (Q) or disabling the buffer, forcing the output into a high impedance state (three-state).

This high-impedance state allows the designer to connect the μPB8212 directly to the microprocessor bi-directional data bus.

Control Logic

The μPB8212 has four control inputs: $\overline{DS}_1$, DS_2, MD and STB. These inputs are employed to control device selection, data latching, output buffer state and the service request flip-flop.

$\overline{DS}_1$, DS_2 (Device Select)

These two inputs are employed for device selection. When $\overline{DS}_1$ is low and DS_2 is high ($\overline{DS}_1 \cdot DS_2$) the device is selected. In the selected state the output buffer is enabled and the service request flip-flop (SR) is asynchronously set.

Service Request Flip-Flop (SR)

The (SR) flip-flop is employed to generate and control interrupts in microcomputer systems. It is asynchronously set by the $\overline{CLR}$ input (active low). When the (SR) flip-flop is set it is in the non-interrupting state.

The output (Q) of the (SR) flip-flop is connected to an inverting input of a "NOR" gate. The other input of the "NOR" gate is non-inverting and is connected to the device selection logic ($\overline{DS}_1 \cdot DS_2$). The output of the "NOR" gate ($\overline{INT}$) is active low (interrupting state) for connection to active low input priority generating circuits.

MD (Mode)

This input is employed to control the state of the output buffer and to determine the source of the clock input (C) to the data latch.

When MD is in the output mode (high) the output buffers are enabled and the source of clock (C) to the data latch is from the device selection logic ($\overline{DS}_1 \cdot DS_2$).

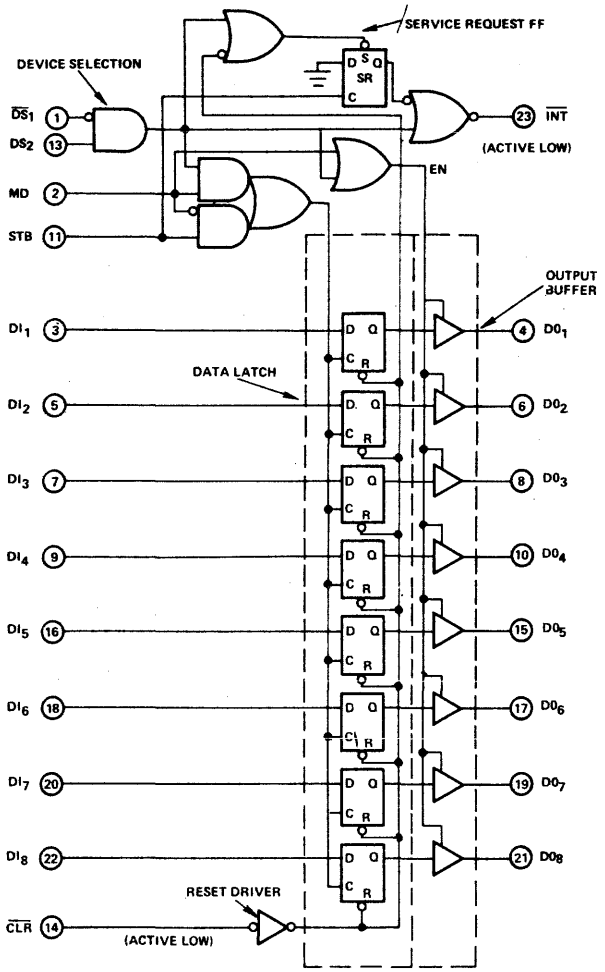
When MD is in the input mode (low) the output buffer state is determined by the device selection logic ($\overline{DS}_1 \cdot DS_2$) and the source of clock (C) to the data latch is the STB (Strobe) input.

STB (Strobe)

STB is employed as the clock (C) to the data latch for the input mode (MD = 0) and to synchronously reset the service request flip-flop (SR).

Note that the SR flip-flop triggers on the negative edge of STB which overrides $\overline{CLR}$.

ABSOLUTE MAXIMUM RATINGS*



Operating Temperature	0°C to +70°C

4 BIT PARALLEL BIDIRECTIONAL BUS DRIVER

DESCRIPTION All inputs are low power TTL compatible. For driving MOS, the DO outputs provide a high 3.65V (V_{OH}), and for high capacitance terminated bus structures, the DB outputs provide a high 55 mA (I_{OL}) capability.

FEATURES
- Data Bus Buffer Driver for μCOM-8 Microprocessor Family
- Low Input Load Current — 0.25 mA Maximum
- High Output Drive Capability for Driving System Data Bus
- 3.65V Output High Voltage for Direct Interface to μCOM-8 Microprocessor Family
- Three State Outputs
- Reduces System Package Count
- Available in 16 pin packages: Cerdip and Plastic

PIN CONFIGURATION

PIN NAMES

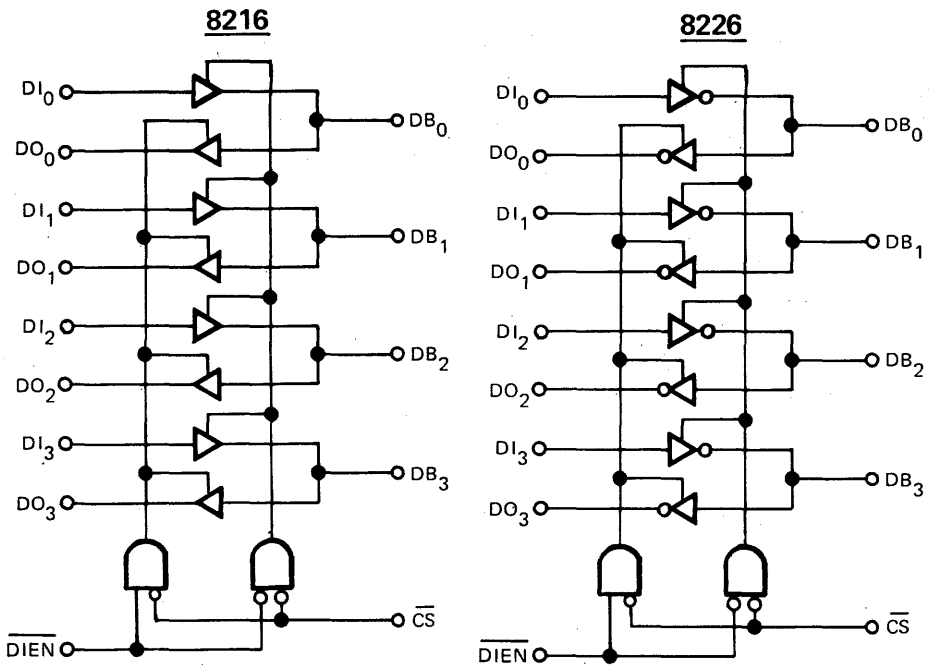
FUNCTIONAL DESCRIPTION

Microprocessors like the 8080A are MOS devices and are generally capable of driving a single TTL load. This also applies to MOS memory devices. This type of drive is sufficient for small systems with a few components, but often it is necessary to buffer the microprocessor and memories when adding components or expanding to a multi-board system.

The μPD8216/8226 is a four bit bi-directional bus driver specifically designed to buffer microcomputer system components.

Bi-Directional Driver

Each buffered line of the four bit driver consists of two separate buffers. They are three state in nature to achieve direct bus interface and bi-directional capability. On one side of the driver the output of one buffer and the input of another are tied together (DB), this is used to interface to the system side components such as memories, I/O, etc. Its interface is directly TTL compatible and it has high drive (55 mA). For maximum flexibility on the other side of the driver the inputs and outputs are separate. They can be tied together so that the driver can be used to buffer a true bi-directional bus such as the 8080A Data Bus. The DO outputs on this side of the driver have a special high voltage output drive capability (3.65V) so that direct interface to the 8080A processor is achieved with an adequate amount of noise immunity (650 mV worst case).



Control Gating $\overline{CS}$, $\overline{DIEN}$

The $\overline{CS}$ input is used for device selection. When $\overline{CS}$ is "high" the output drivers are all forced to their high-impedance state. When it is "low" the device is selected (enabled) and the data flow direction is determined by the $\overline{DIEN}$ input.

The $\overline{DIEN}$ input controls the data flow direction (see Block Diagrams for complete truth table). This directional control is accomplished by forcing one of the pair of buffers to its high impedance state. This allows the other to transmit its data. This is accomplished by a simple two gate circuit.

The μPB8216/8226 is a device that will reduce component count in microcomputer systems and at the same time enhance noise immunity to assure reliable, high performance operation.

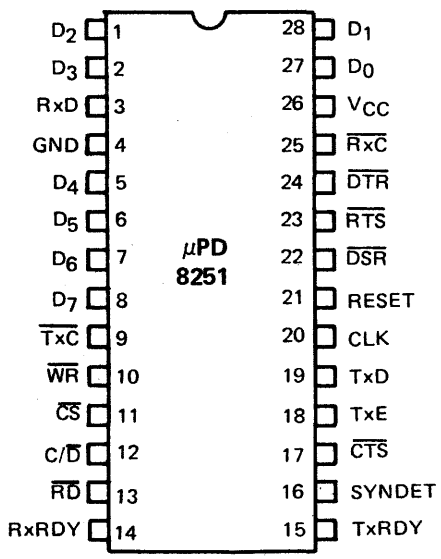
PROGRAMMABLE COMMUNICATION INTERFACE



DESCRIPTION

The μPD8251 Universal Synchronous/Asynchronous Receiver/Transmitter (USART) is designed for microcomputer systems data communications. The USART is used as a peripheral and is programmed by the μPD8080 or other processor to communicate in commonly used serial data transmission techniques including IBM Bi-Sync. The USART receives serial data streams and converts them into parallel data characters for the processor. While receiving serial data, the USART will also accept data characters from the processor in parallel format, convert them to serial format and transmit. The USART will signal the processor when it has completely received or transmitted a character and requires service. Complete USART STATUS including data format errors and control signals such as TxE and SYNDET is available to the processor at any time.

FEATURES

- Asynchronous or Synchronous Operation
  - Asynchronous:
    - 5-8 Bit Characters
    - Clock Rate – 1, 16 or 64 x Baud Rate
    - Break Character Generation
    - Select 1, 1-1/2, or 2 Stop Bits
    - False Start Bit Detector
  - Synchronous:
    - 5-8 Bit Characters
    - Internal or External Character Synchronization
    - Automatic Sync Insertion
    - Single or Double Sync Characters
- Baud Rate – Synchronous – DC to 56K Baud
  – Asynchronous – DC to 9.6K Baud
- Full Duplex, Double Buffered Transmitter and Receiver
- Parity, Overrun and Framing Flags
- Fully Compatible with 8080
- All Inputs and Outputs are TTL Compatible
- Single +5 Volt Supply
- Separate Device, Receive and Transmit TTL Clocks
- 28 Pin Plastic DIP Package
- N-Channel MOS Technology

PIN CONFIGURATION

PIN NAMES

FUNCTIONAL DESCRIPTION

The μPD8251 Universal Synchronous/Asynchronous Receiver/Transmitter is designed specifically for 8080 microcomputer systems but works with most 8-bit processors. Operation of the 8251, like other I/O devices in the 8080 family, is programmed by system software for maximum flexibility.

In the receive mode, a communication interface device must convert incoming serial format data into parallel data and make certain format checks on the data. And in the transmit mode, the device must format data into serial data. The device must also supply or remove characters or bits that are unique to the communication format in use. By performing conversion and formatting services automatically, the USART appears to the processor as a simple or "transparent" input or output of byte-oriented parallel data.

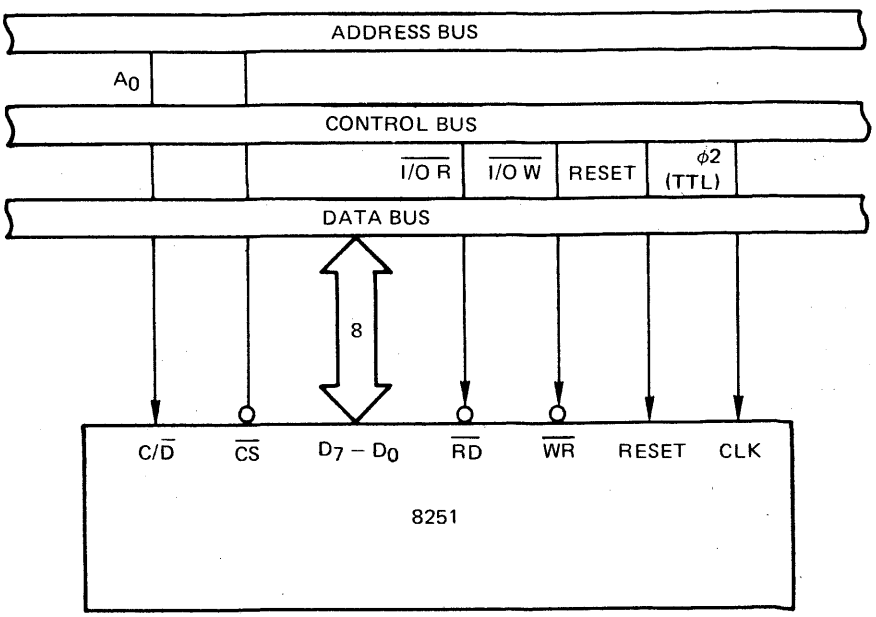
26	V_{CC}	V_{CC} Supply Voltage	+5 volt supply
4	GND	Ground	Ground
Read/Write Control Logic			This logic block accepts inputs from the processor Control Bus and generates control signals for overall USART operation. The Mode Instruction and Command Instruction registers that store the control formats for device functional definition are located in the Read/ Write Control Logic.
21	RESET	Reset	A "one" on this input forces the USART into the "Idle" mode where it will remain until reinitialized with a new set of control words. Minimum RESET pulse width is t_{CY}.
20	CLK	Clock Pulse	The CLK input provides for internal device timing and is usually connected to the Phase 2 (TTL) output of the μPB8224 Clock Generator. External inputs and outputs are not referenced to CLK, but the CLK frequency must be 30 times the Receiver or Transmitter clocks in the synchronous mode and 4.5 times for the asynchronous mode.
10	$\overline{WR}$	Write Data	A "zero" on this input instructs the μPD8251 to accept the data or control word which the processor is writing out to the USART via the data bus.
13	$\overline{RD}$	Read Data	A "zero" on this input instructs the μPD8251 to place the data or status information onto the Data Bus for the processor to read.
12	C/$\overline{D}$	Control/Data	The Control/Data input, in conjunction with the $\overline{WR}$ and $\overline{RD}$ inputs, informs USART to accept or provide either a data-character, control word or status information via the Data Bus. 0 = Data; 1 = Control.
11	$\overline{CS}$	Chip Select	A "zero" on this input enables the USART for reading and writing to the processor.
Modem Control			The μPD8251 has a set of control inputs and outputs which may be used to simplify the interface to a Modem.
22	$\overline{DSR}$	Data Set Ready	The Data Set Ready input can be tested by the processor via Status information. The $\overline{DSR}$ input is normally used to test Modem Data Set Ready condition.
24	$\overline{DTR}$	Data Terminal Ready	The Data Terminal Ready output can be controlled via the Command word. The $\overline{DTR}$ output is normally used to drive Modem Data Terminal Ready or Rate Select lines.
23	$\overline{RTS}$	Request to Send	The Request to Send output can be controlled via the Command word. The $\overline{RTS}$ output is normally used to drive the Modem Request to Send line.
17	$\overline{CTS}$	Clear to Send	A "zero" on the Clear to Send input enables the USART to transmit serial data if the TxEN bit in the Command Instruction register is enabled (one).

©IC MASTER 1978



TRANSMIT BUFFER/ CONVERTER

The Transmit Buffer/Converter receives parallel data from the Data Bus Buffer via the internal data bus, converts parallel to serial data, inserts the necessary characters or bits needed for the programmed communication format and outputs composite serial data on the TxD output.

PIN IDENTIFICATION (CONT.)

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
Transmit Control Logic			The Transmit Control Logic accepts and outputs all external and internal signals necessary for serial data transmission.
15	TxRDY	Transmitter Ready	Transmitter Ready signals the processor that the transmitter is ready to accept a data character. TxRDY can be used as an interrupt or may be tested through the Status information for Polled operation. Loading a character from the processor automatically resets TxRDY.
18	TxE	Transmitter Empty	The Transmitter Empty output signals the processor that the USART has no further characters to transmit. TxE is automatically reset upon receiving a data character from the processor. In half-duplex, TxE can be used to signal end of a transmission and request the processor to "turn the line around." The TxEn bit in the command instruction does not effect TxE. In the Synchronous mode, a "one" on this output indicates that a Sync character or characters are about to be automatically transmitted as "fillers" because the next data character has not been loaded.
9	$\overline{TxC}$	Transmitter Clock	The Transmitter Clock controls the serial character transmission rate. In the Asynchronous mode, the $\overline{TxC}$ frequency is a multiple of the actual Baud Rate. Two bits of the Mode Instruction select the multiple to be 1x, 16x, or 64x the Baud Rate. In the Synchronous mode, the $\overline{TxC}$ frequency is automatically selected to equal the actual Baud Rate. Note that for both Synchronous and Asynchronous modes, serial data is shifted out of the USART by the falling edge of $\overline{TxC}$.
19	TxD	Transmitter Data	The Transmit Control Logic outputs the composite serial data stream on this pin.

8251 INTERFACE TO 8080 STANDARD SYSTEM BUS

©IC MASTER 1978

RECEIVER BUFFER

The Receiver Buffer accepts serial data input at the $\overline{RxD}$ pin and converts the data from serial to parallel format. Bits or characters required for the specific communication technique in use are checked and then an eight-bit "assembled" character is readied for the processor. For communication techniques which require less than eight bits, the μPD8251 sets the extra bits to "zero."

PIN IDENTIFICATION (CONT.)

PIN NO.	PIN SYMBOL	PIN NAME	FUNCTION
Receiver Control Logic			This block manages all activities related to incoming data.
14	RxRDY	Receiver Ready	The Receiver Ready output indicates that the Receiver Buffer is ready with an "assembled" character for input to the processor. For Polled operation, the processor can check RxRDY using a Status Read or RxRDY can be connected to the processor interrupt structure. Note that reading the character to the processor automatically resets RxRDY.
25	$\overline{RxC}$	Receiver Clock	The Receiver Clock is the rate at which the incoming character is received. In the Asynchronous mode, the $\overline{RxC}$ frequency may be 1,16 or 64 times the actual Baud Rate but in the Synchronous mode the $\overline{RxC}$ frequency must equal the Baud Rate. Two bits in the mode instruction select Asynchronous at 1x, 16x or 64x or Synchronous operation at 1x the Baud Rate. Unlike $\overline{TxC}$, data is sampled by the μPD8251 on the rising edge of $\overline{RxC}$. (1)
3	RxD	Receiver Data	A composite serial data stream is received by the Receiver Control Logic on this pin.
16	SYNDET	Sync Detect	The SYNC Detect pin is only used in the Synchronous mode. The μPD8251 may be programmed through the Mode Instruction to operate in either the internal or external Sync mode and SYNDET then functions as an output or input respectively. In the internal Sync mode, the SYNDET output will go to a "one" when the μPD8251 has located the SYNC character in the Receive mode. If double SYNC character (bi-sync) operation has been programmed, SYNDET will go to "one" in the middle of the last bit of the second SYNC character. SYNDET is automatically reset to "zero" upon a Status Read or RESET. In the external SYNC mode, a "zero" to "one" transition on the SYNDET input will cause the μPD8251 to start assembling data character on the next falling edge of $\overline{RxC}$. The length of the SYNDET input should be at least one $\overline{RxC}$ period, but may be removed once the μPD8251 is in SYNC.

Note: (1) Since the μPD8251 will frequently be handling both the reception and transmission for a given link, the Receive and Transmit Baud Rates will be same. $\overline{RxC}$ and $\overline{TxC}$ then require the same frequency and may be tied together and connected to a single clock source or Baud Rate Generator.

Examples:

If the Baud Rate equals 110 (Async):
- $\overline{RxC}$ or $\overline{TxC}$ equals 110 Hz (1x)
- $\overline{RxC}$ or $\overline{TxC}$ equals 1.76 KHz (16x)
- $\overline{RxC}$ or $\overline{TxC}$ equals 7.04 KHz (64x)

If the Baud Rate equals 300:
- $\overline{RxC}$ or $\overline{TxC}$ equals 300 Hz (1x) A or S
- $\overline{RxC}$ or $\overline{TxC}$ equals 4800 Hz (16x) A only
- $\overline{RxC}$ or $\overline{TxC}$ equals 19.2 KHz (64x) A only

©IC MASTER 1978

OPERATIONAL DESCRIPTION

A set of control words must be sent to the μPD8251 to define the desired mode and communications format. The control words will specify the BAUD RATE FACTOR (1x, 16x, 64x), CHARACTER LENGTH (5 to 8), NUMBER OF STOP BITS (1, 1-1/2, 2), ASYNCHRONOUS or SYNCHRONOUS MODE, SYNDET (IN or OUT), PARITY, etc.

After receiving the control words, the μPD8251 is ready to communicate. TxRDY is raised to signal the processor that the USART is ready to receive a character for transmission. When the processor writes a character to the USART, TxRDY is automatically reset.

Concurrently, the μPD8251 may receive serial data; and after receiving an entire character, the RxRDY output is raised to indicate a completed character is ready for the processor. The processor fetch will automatically reset RxRDY.

Note: The μPD8251 may provide faulty RxRDY for the first read after power-on or for the first read after receive is re-enabled by a command instruction (RxE). A dummy read is recommended to clear faulty RxRDY. But this is not the case for the first read after hardware or software reset after the device operation has once been established.

The μPD8251 cannot transmit until the TxEN (Transmitter Enable) bit has been set by a Command Instruction and until the $\overline{CTS}$ (Clear to Send) input is a "zero". TxD is held in the "marking" state after Reset awaiting new Command Words.

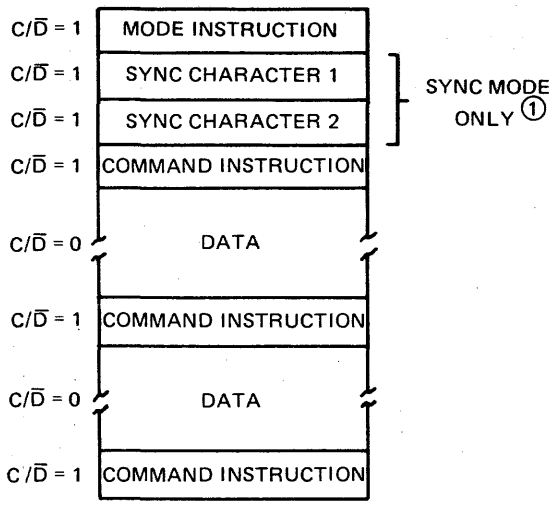
μPD8251 PROGRAMMING

The USART must be loaded with a group of two to four control words provided by the processor before data reception and transmission can begin. A Reset (internal or external) must immediately proceed the control words which are used to program the complete operational description of the communications interface. If an external RESET is not available, three successive 00 Hex or two successive 80 Hex command instructions ($C/\overline{D}$ = 1) followed by a software reset command instruction (40 Hex) can be used to initialize the 8251.

There are two control word formats:

1. Mode Instruction
2. Command Instruction

MODE INSTRUCTION



This control word specifies the general characteristics of the interface regarding the SYNCHRONOUS or ASYNCHRONOUS MODE, BAUD RATE FACTOR, CHARACTER LENGTH, PARITY, and NUMBER OF STOP BITS. Once the Mode Instruction has been received, SYNC characters or Command Instructions may be inserted depending on the Mode Instruction content.

COMMAND INSTRUCTION

This control word will be interpreted as a SYNC character definition if immediately preceded by a Mode Instruction which specified a Synchronous format. After the SYNC character(s) are specified or after an Asynchronous Mode Instruction, all subsequent control words will be interpreted as an update to the Command Instruction. Command Instruction updates may occur at any time during the data block. To modify the Mode Instruction, a bit may be set in the Command Instruction which causes an internal Reset which allows a new Mode Instruction to be accepted.

©IC MASTER 1978

TYPICAL DATA BLOCK

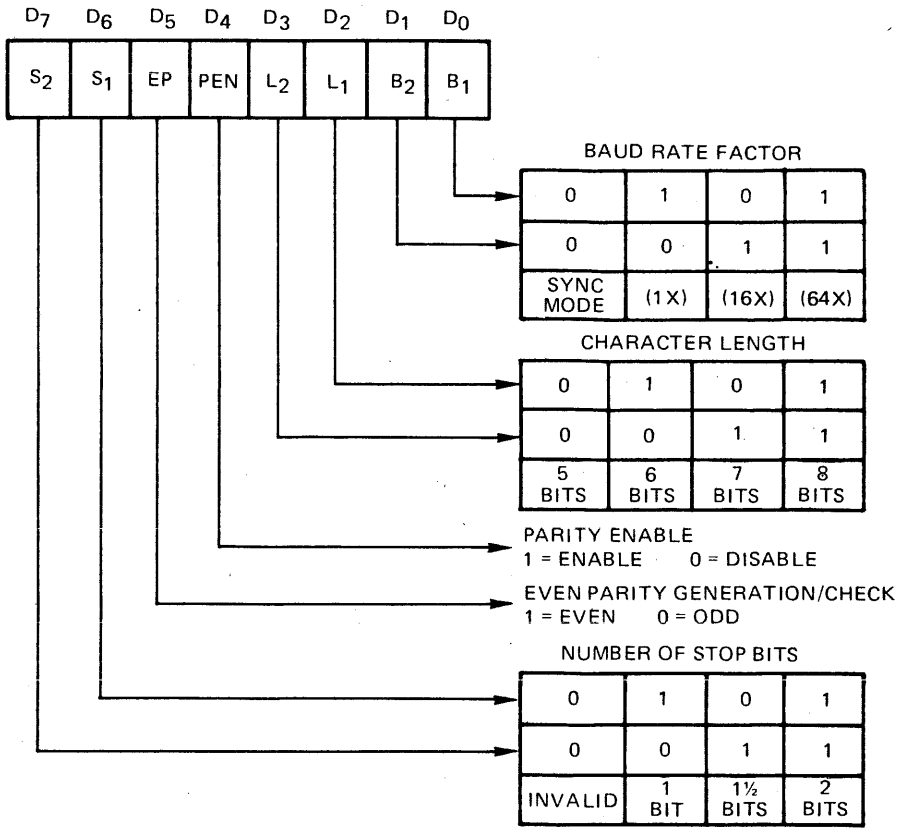
NOTE ① The second SYNC character is skipped if MODE instruction has programmed the 8251 to single character Internal SYNC Mode. Both SYNC characters are skipped if MODE instruction has programmed the 8251 to ASYNC mode.

MODE INSTRUCTION DEFINITION

The μPD8251 can operate in either Asynchronous or Synchronous communication modes. Understanding how the Mode Instruction controls the functional operation of the USART is easiest when the device is considered to be two separate components, one asynchronous and the other synchronous, which share the same support circuits and package. Although the format definition can be changed at will or "on the fly", the two modes will be explained separately for clarity.

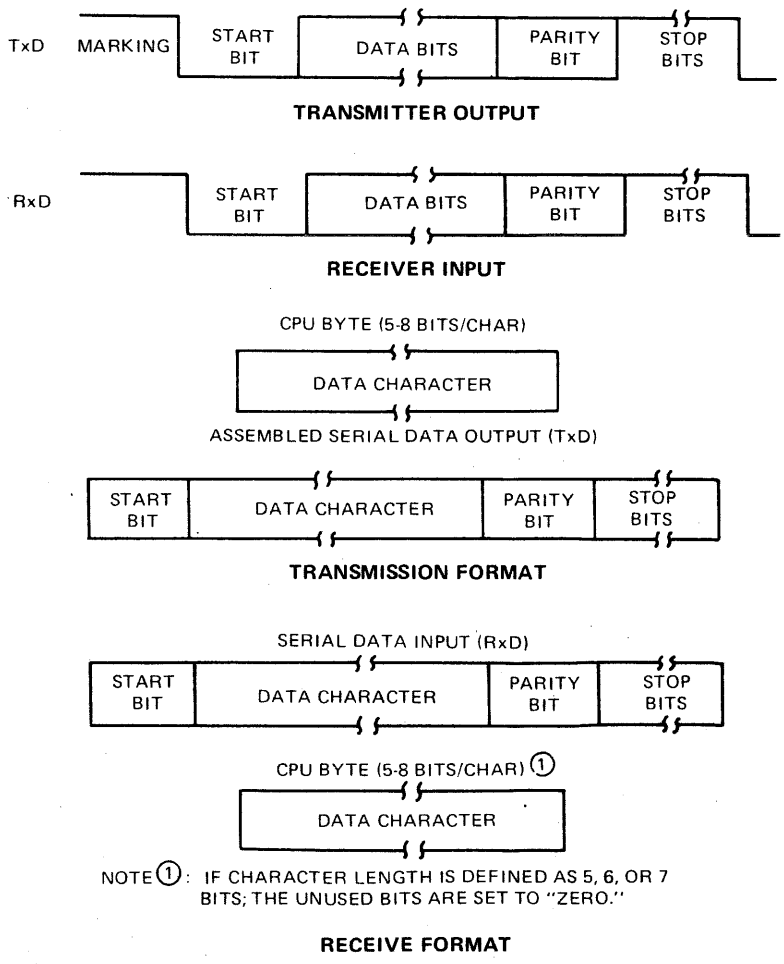
ASYNCHRONOUS TRANSMISSION

When a data character is written into the μPD8251, the USART automatically adds a START bit (low level or "space") and the number of STOP bits (high level or "mark") specified by the Mode Instruction. If Parity has been enabled, an odd or even Parity bit is inserted just before the STOP bits(s), as specified by the Mode Instruction. Then, depending on $\overline{CTS}$ and TxEN, the character may be transmitted as a serial data stream at the TxD output. Data is shifted out by the falling edge of $\overline{TxC}$ at $\overline{TxC}$, $\overline{TxC}$/16 or $\overline{TxC}$/64, as defined by the Mode Instruction.



If no data characters have been loaded into the μPD8251, or if all available characters have been transmitted, the TxD output remains "high" (marking) in preparation for sending the START bit of the next character provided by the processor. TxD may be forced to send a BREAK (continuously low) by setting the correct bit in the Command Instruction.

ASYNCHRONOUS RECEIVE



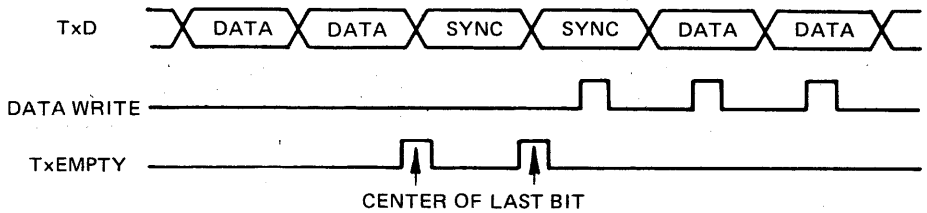
The RxD input line is normally held "high" (marking) by the transmitting device. A falling edge at RxD signals the possible beginning of a START bit and a new character. The START bit is checked by testing for a "low" at its nominal center as specified by the BAUD RATE. If a "low" is detected again, it is considered valid, and the bit assembling counter starts counting. The bit counter locates the approximate center of the data, parity (if specified), and STOP bits. The parity error flag (PE) is set, if a parity error occurs. Input bits are sampled at the RxD pin with the rising edge of $\overline{RxC}$. If a high is not detected for the STOP bit, which normally signals the end of an input character, a framing error (FE) will be set. After a valid STOP bit, the input character is loaded into the parallel Data Bus Buffer of the μPD8251 and the RxRDY signal is raised to indicate to the processor that a character is ready to be fetched. If the processor has failed to fetch the previous character, the new character replaces the old and the overrun flag (OE) is set. All the error flags can be reset by setting a bit in the Command Instruction. Error flag conditions will not stop subsequent USART operation.

©IC MASTER 1978

MODE INSTRUCTION FORMAT ASYNCHRONOUS MODE

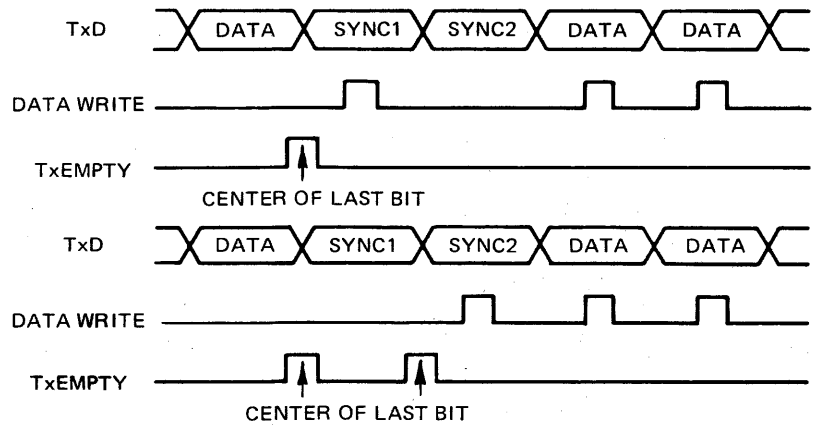
TRANSMIT/RECEIVE FORMAT ASYNCHRONOUS MODE

©IC MASTER 1978



SYNCHRONOUS TRANSMISSION

As in Asynchronous transmission, the TxD output remains "high" (marking) until the μPD8251 receives the first character from the processor which is usually a SYNC character. After a Command Instruction has set TxEN and after Clear to Send ($\overline{CTS}$) goes low, the first character is serially transmitted. Data is shifted out on the falling edge of $\overline{TxC}$ and the same rate as $\overline{TxC}$.



Once transmission has started, Synchronous Mode format requires that the serial data stream at TxD continue at the $\overline{TxC}$ rate or SYNC will be lost. If a data character is not provided by the processor before the μPD8251 Transmitter Buffer becomes empty, the SYNC character(s) loaded directly following the Mode Instruction will be automatically inserted in the TxD data stream. The SYNC character(s) are inserted to fill the line and maintain synchronization until new data characters are available for transmission. If the μPD8251 becomes empty, and must send the SYNC character(s), the TxEMPTY output is raised to signal the processor that the Transmitter Buffer is empty and SYNC characters are being transmitted. TxEMPTY is automatically reset by the next character from the processor.

TxEMPTY go high at the middle of the last data bit when the Transmit Register is EMPTY. TxEMPTY goes low again as sync characters are transmitted. See figure below.

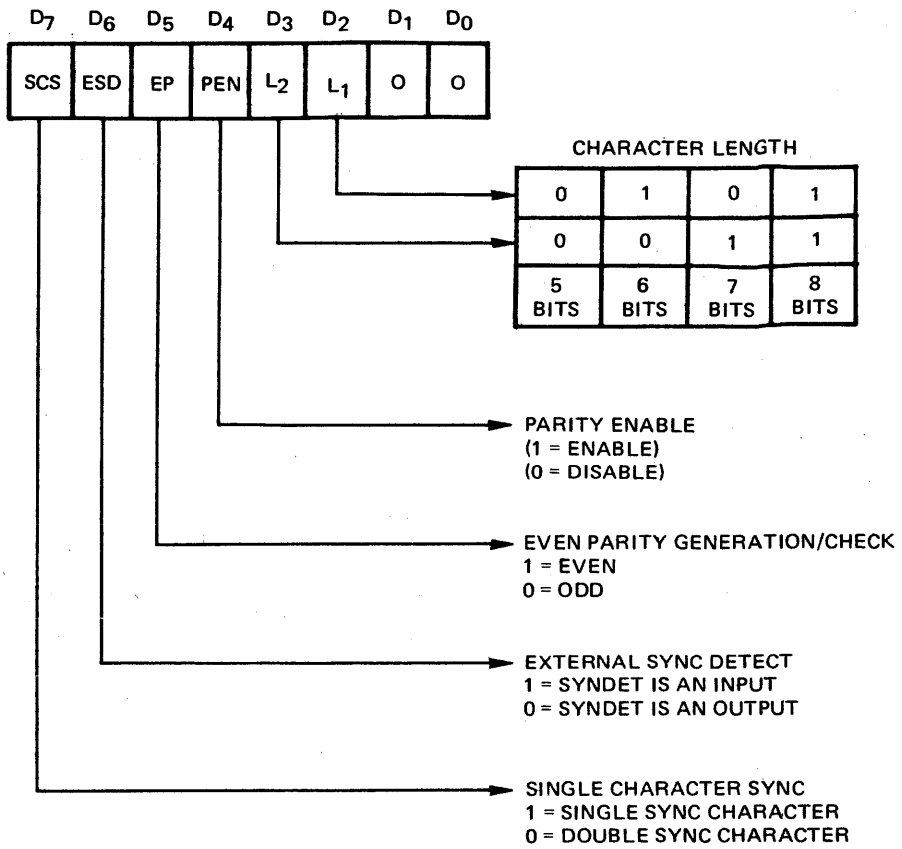
FOR SINGLE SYNC CHARACTER OPERATION

FOR DOUBLE SYNC CHARACTER OPERATION (BISYNC)

SYNCHRONOUS RECEIVE

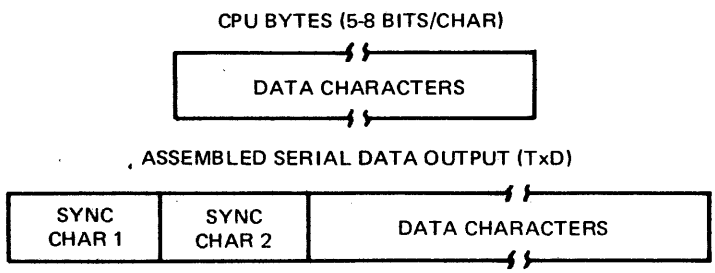
In Synchronous Receive, character synchronization can be either external or internal. If the internal SYNC mode has been selected, and the Enter HUNT (EH) bit has been set by a Command Instruction, the receiver goes into the HUNT mode.

Incoming data on the RxD input is sampled on the rising edge of $\overline{RxC}$, and the Receiver Buffer is compared with the first SYNC character after each bit has been loaded until a match is found. If two SYNC characters have been programmed, the next received character is also compared. When the SYNC character(s) programmed have been detected, the μPD8251 leaves the HUNT mode and is in character synchronization. At this time, the SYNDET (output) is set high. SYNDET is automatically reset by a STATUS READ.



If external SYNC has been specified in the Mode Instruction, a "one" applied to the SYNDET (input) for at least one $\overline{RxC}$ cycle will synchronize the USART.

Parity and Overrun Errors are treated the same in the Synchronous as in the Asynchronous Mode. Framing errors do not apply in the Synchronous format.



The processor may command the receiver to enter the HUNT mode with a Command Instruction which sets Enter HUNT (EH) if synchronization is lost.

MODE INSTRUCTION FORMAT SYNCHRONOUS MODE

TRANSMIT/RECEIVE FORMAT SYNCHRONOUS MODE

TRANSMIT FORMAT

RECEIVE FORMAT

©IC MASTER 1978

COMMAND INSTRUCTION FORMAT

After the functional definition of the μPD8251 has been specified by the Mode Instruction and the SYNC character(s) have been entered, if in SYNC mode, the USART is ready to receive Command Instructions and begin communication. A Command Instruction is used to control the specific operation of the format selected by the Mode Instruction. Enable Transmit, Enable Receive, Error Reset and Modem Controls are controlled by the Command Instruction.

After the Mode Instruction and the SYNC character(s), as needed, are loaded, all subsequent "control writes" ($C/\overline{D} = 1$) will load or overwrite the Command Instruction register. A Reset operation (internal via CMD IR or external via the RESET input) will cause the μPD8251 to interpret the next "control write", which must immediately follow the reset, as a Mode Instruction.

STATUS READ FORMAT

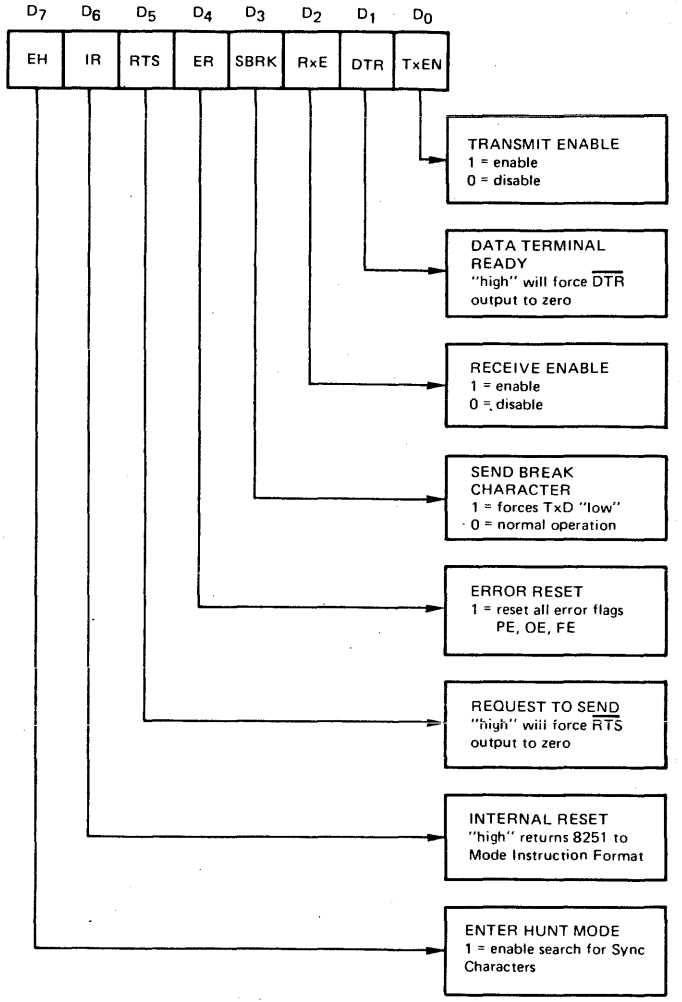
It is frequently necessary for the processor to examine the "status" of an active interface device to determine if errors have occurred or to notice other conditions which require a response from the processor. The μPD8251 has features which allow the processor to "read" the device status at any time. A data fetch is issued by the processor while holding the $C/\overline{D}$ input "high" to obtain device Status Information. Many of the bits in the status register are copies of external pins. This dual status arrangement allows the μPD8251 to be used in both Polled and interrupt driven environments. Status update can have a maximum delay of a 16 clock period.

PARITY ERROR

When a parity error is detected, the PE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. PE being set does not inhibit USART operation.

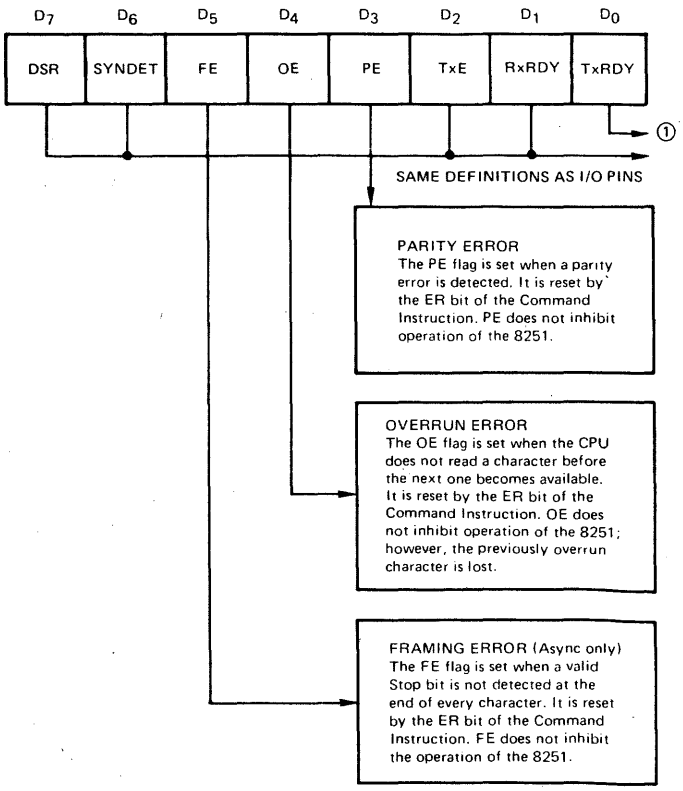
OVERRUN ERROR

If the processor fails to read a data character before the one following is available, the OE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. Although OE being set does not inhibit USART operation, the previously received character is overwritten and lost.



FRAMING ERROR ①

If a valid STOP bit is not detected at the end of a character, the FE flag is set, and is cleared by setting the ER bit in a subsequent Command Instruction. FE being set does not inhibit USART operation.



Note: ① ASYNC mode only.

DESCRIPTION

The μPD8255 is a general purpose programmable INPUT/OUTPUT device designed for use with the 8080A microprocessor. Twenty-four (24) I/O lines may be programmed in two groups of twelve (group I and group II) and used in three major modes of operation. In the Basic mode, (MODE 0), each group of twelve I/O pins may be programmed in a set of 8 and a set of 4 to be input or output. In the Strobed mode, (MODE 1), each group may be programmed to have 8 lines of input or output. Three of the remaining four pins in each group are used for handshaking strobes and interrupt control signals. The Bidirectional Bus mode, (MODE 2), uses the 8 lines of Port A for a bidirectional bus, and five lines from Port C for bus control signals. The μPD8255 is packaged in a 40 pin plastic DIP.

FEATURES

- Fully Compatible with the 8080A Microprocessor Family
- All Inputs and Outputs TTL Compatible
- 24 Programmable I/O Pins
- Direct Bit SET/RESET Eases Control Application Interfaces
- 8 – 2 mA Darlington Drive Outputs for Printers and Displays
- LSI Drastically Reduces System Package Count
- Standard 40 Pin Dual-In-Line Plastic Package

FUNCTIONAL DESCRIPTION

General

The μPD8255 Programmable Peripheral Interface (PPI) is designed for use in 8080A microprocessor systems. Peripheral equipment can be effectively and efficiently interfaced to the 8080A data and control busses with the μPD8255. The μPD8255 is functionally configured to be programmed by system software to avoid external logic for peripheral interfaces.

Data Bus Buffer

The 3-state, bidirectional, eight bit Data Bus Buffer (D_0-D_7) of the μPD8255 can be directly interfaced to the 8080A system Data Bus (D_0-D_7). The Data Bus Buffer is controlled by execution of IN and OUT instructions by the 8080A. Control Words and Status information are also transmitted via the Data Bus Buffer.

Read/Write and Control Logic

This block manages all of the internal and external transfers of Data, Control and Status. Through this block, the processor Address and Control busses can control the peripheral interfaces.

Chip Select, $\overline{CS}$, pin 6

A Logic Low, V_{IL}, on this input enables the μPD8255 for communication with the 8080A.

Read, $\overline{RD}$, pin 5

A Logic Low, V_{IL}, on this input enables the μPD8255 to send Data or Status to the processor via the Data Bus Buffer.

Write, $\overline{WR}$, pin 36

A Logic Low, V_{IL}, on this input enables the Data Bus Buffer to receive Data or Control Words from the processor.

Port Select 0, A_0, pin 9

Port Select 1, A_1, pin 8

These two inputs are used in conjunction with $\overline{CS}$, $\overline{RD}$, and $\overline{WR}$ to control the selection of one of three ports on the Control Word Register. A_0 and A_1 are usually connected to A_0 and A_1 of the processor Address Bus.

Reset, pin 35

A Logic High, V_{IH}, on this input clears the Control Register and sets ports A, B, and C to the input mode, The input latches in ports A, B, and C are not cleared.

Group I and Group II Controls

Through an OUT instruction in System Software from the processor, a control word is transmitted to the μPD8255. Information such as "MODE," "Bit SET," and "Bit RESET" is used to initialize the functional configuration of each I/O port.

Each group (I and II) accepts "commands" from the Read/Write Control Logic and "control words" from the internal data bus and in turn controls its associated I/O ports.

Group I – Port A and upper Port C (PC_7-PC_4)

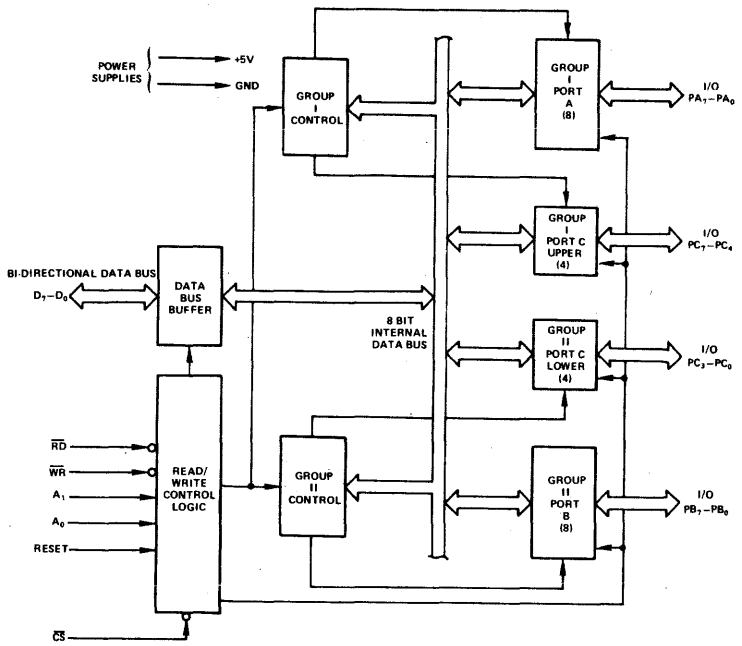
Group II – Port B and lower Port C (PC_3-PC_0)

While the Control Word Register can be written into, the contents can not be read back to the processor.

Ports A, B, and C

The three 8-bit I/O ports (A, B, and C) in the μPD8255 can all be configured to meet a wide variety of functional requirements through system software. The effectiveness and flexibility of the μPD8255 is further enhanced by special features unique to each of the ports.

Port A = An 8-bit data output latch/buffer and data input latch.



Port B = An 8-bit data input/output latch/buffer and an 8-bit data input buffer.

Port C = An 8-bit output latch/buffer and a data input buffer (input not latched).

Port C may be divided into two independent 4 bit control and status ports for use with Ports A & B.

NEC Microcomputers

The μPD8255 can be operated in modes (0, 1 or 2) which are selected by appropriate control words and are detailed below.

MODES

MODE 0

- MODE 0 provides for basic Input and Output operations through each of the ports A, B, and C. Output data is latched and input data follows the peripheral. No "handshaking" strobes are needed.
- 16 different configurations in MODE 0
- Two 8-bit ports and two 4-bit ports
- Inputs are not latched
- Outputs are latched

MODE 1

- MODE 1 provides for Strobed Input and Output operations with data transferred through Port A or B and handshaking through Port C.
- Two I/O Groups (I and II)
- Both groups contain an 8-bit data port and a 4-bit control/data port
- Both 8-bit data ports can be either Latched Input or Latched Output

MODE 2

- MODE 2 provides for Strobed bidirectional operation using PA_{0-7} as the bidirectional latched data bus. PC_{3-7} is used for interrupts and "handshaking" bus flow controls similar to Mode 1. Note that PB_{0-7} and PC_{0-2} may be defined as Mode 0 or 1, input or output in conjunction with Port A in Mode 2.
- An 8-bit latched bidirectional bus port (PA_{0-7}) and a 5-bit control port (PC_{3-7})
- Both inputs and outputs are latched
- An additional 8-bit input or output port with a 3-bit control port

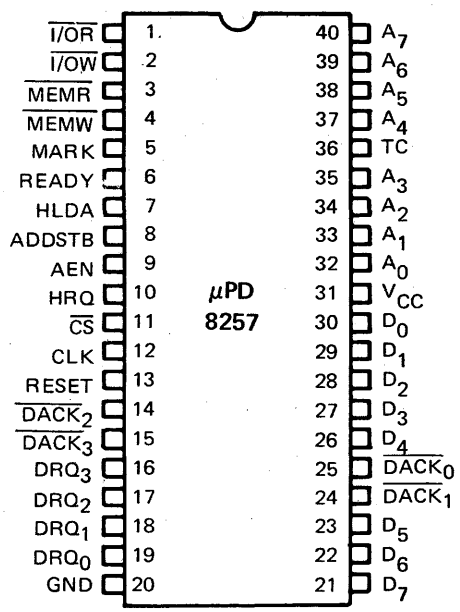
PROGRAMMABLE DMA CONTROLLER



DESCRIPTION

The μPD8257 is a programmable four-channel Direct Memory Access (DMA) controller. It is designed to simplify high speed transfers between peripheral devices and memories. Upon a peripheral request, the 8257 generates a sequential memory address, thus allowing the peripheral to read or write data directly to or from memory. Peripheral requests are prioritized within the 8257 so that the system bus may be acquired by the generation of a single HOLD command to the 8080. DMA cycle counts are maintained for each of the four channels, and a control signal notifies the peripheral when the preprogrammed member of DMA cycles has occurred. Output control signals are also provided which allow simplified sectored data transfers and expansion to other 8257 devices for systems requiring more than four DMA channels.

FEATURES

- Four Channel DMA Controller
- Priority DMA Request Logic
- Channel Inhibit Logic
- Terminal Count and Modulo 128 Outputs
- Automatic Load Mode
- Single TTL Clock
- Single +5V Supply
- Expandable
- 40 Pin Plastic Dual-In-Line Package

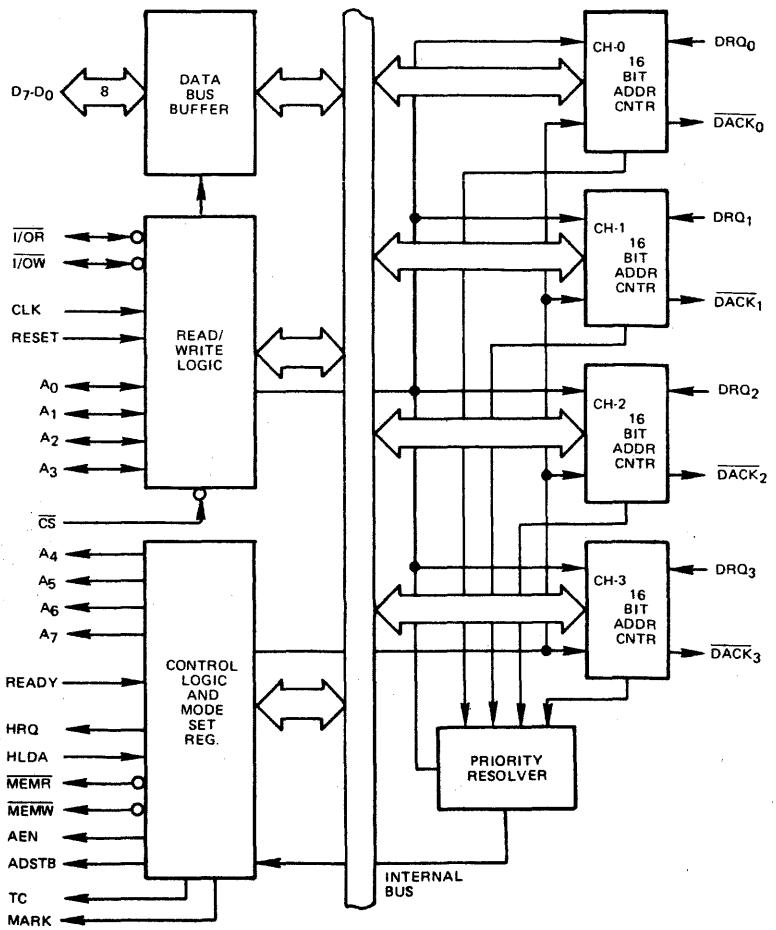
FUNCTIONAL DESCRIPTION

The 8257 is a programmable, Direct Memory Access (DMA) device and when used with an 8212 I/O port device, it provides a complete four-channel DMA controller for use in 8080 based systems. Once initialized by an 8080 CPU, the 8257 will block transfer up to 16,364 bytes of data between memory and a peripheral device without any attention from the CPU, and it will do this on all 4-DMA channels. After receiving a DMA transfer request from a peripheral, the following sequence of events occur within the 8257.

- It acquires control of the system bus (placing 8080 in hold mode).
- Resolves priority conflicts if multiple DMA requests are made.
- A 16 bit memory address word is generated with the aid of an 8212 in the following manner:

  The 8257 outputs the least significant eight bits (A_0-A_7) which go directly onto the address bus.

  The 8257 outputs the most significant eight bits (A_8-A_{15}) onto the data bus where they are latched into an 8212 and then sent to the high order bits on the address bus.
- The appropriate memory and I/O read/write control signals are generated allowing the peripheral to receive or deposit a data byte directly from or to the appropriate memory location.



Block transfer of data (e.g., a sector of data on a floppy disk) either to or from a peripheral may be accomplished as long as the peripheral maintains its DMA Request (DRQ_n). The 8257 retains control of the system bus as long as DRQ_n remains high or until the Terminal Count (TC) is reached. When the Terminal Count occurs, TC goes high, informing the CPU that the operation is complete.

There are three different modes of operation:

- DMA read; which causes data to be transferred from memory to a peripheral;
- DMA write; which causes data to be transferred from a peripheral to memory; and ,
- DMA verify; which does not actually involve the transfer of data.

The DMA read and write modes are the normal operating conditions for the 8257. The DMA verify mode responds in the same manner as read/write except no memory or I/O read/write control signals are generated, thus preventing the transfer of data. The peripheral gains control of the system bus and obtains DMA Acknowledgements for its requests, thus allowing it to access each byte of a data block for check purposes or accumulation of a CRC (Cyclic Redundancy Code) checkword. In some applications it is necessary for a block of DMA read or write cycles to be followed by a block of DMA verify cycles to allow the peripheral to verify its newly acquired data.

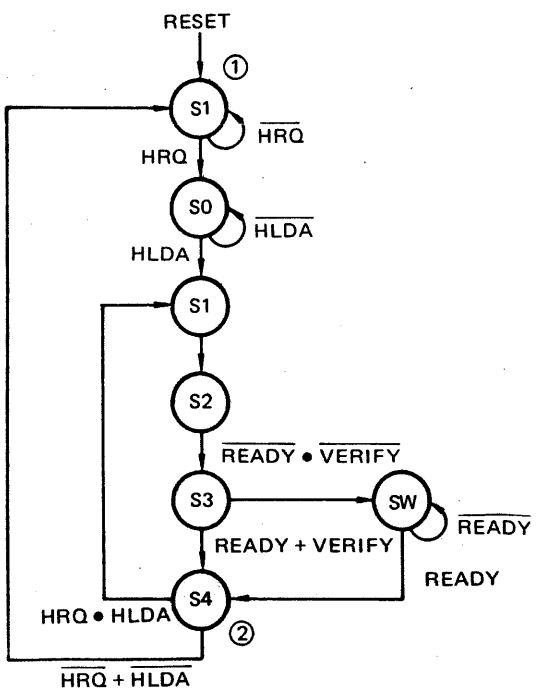
TIMING WAVEFORMS
DMA (MASTER) MODE

DMA OPERATION

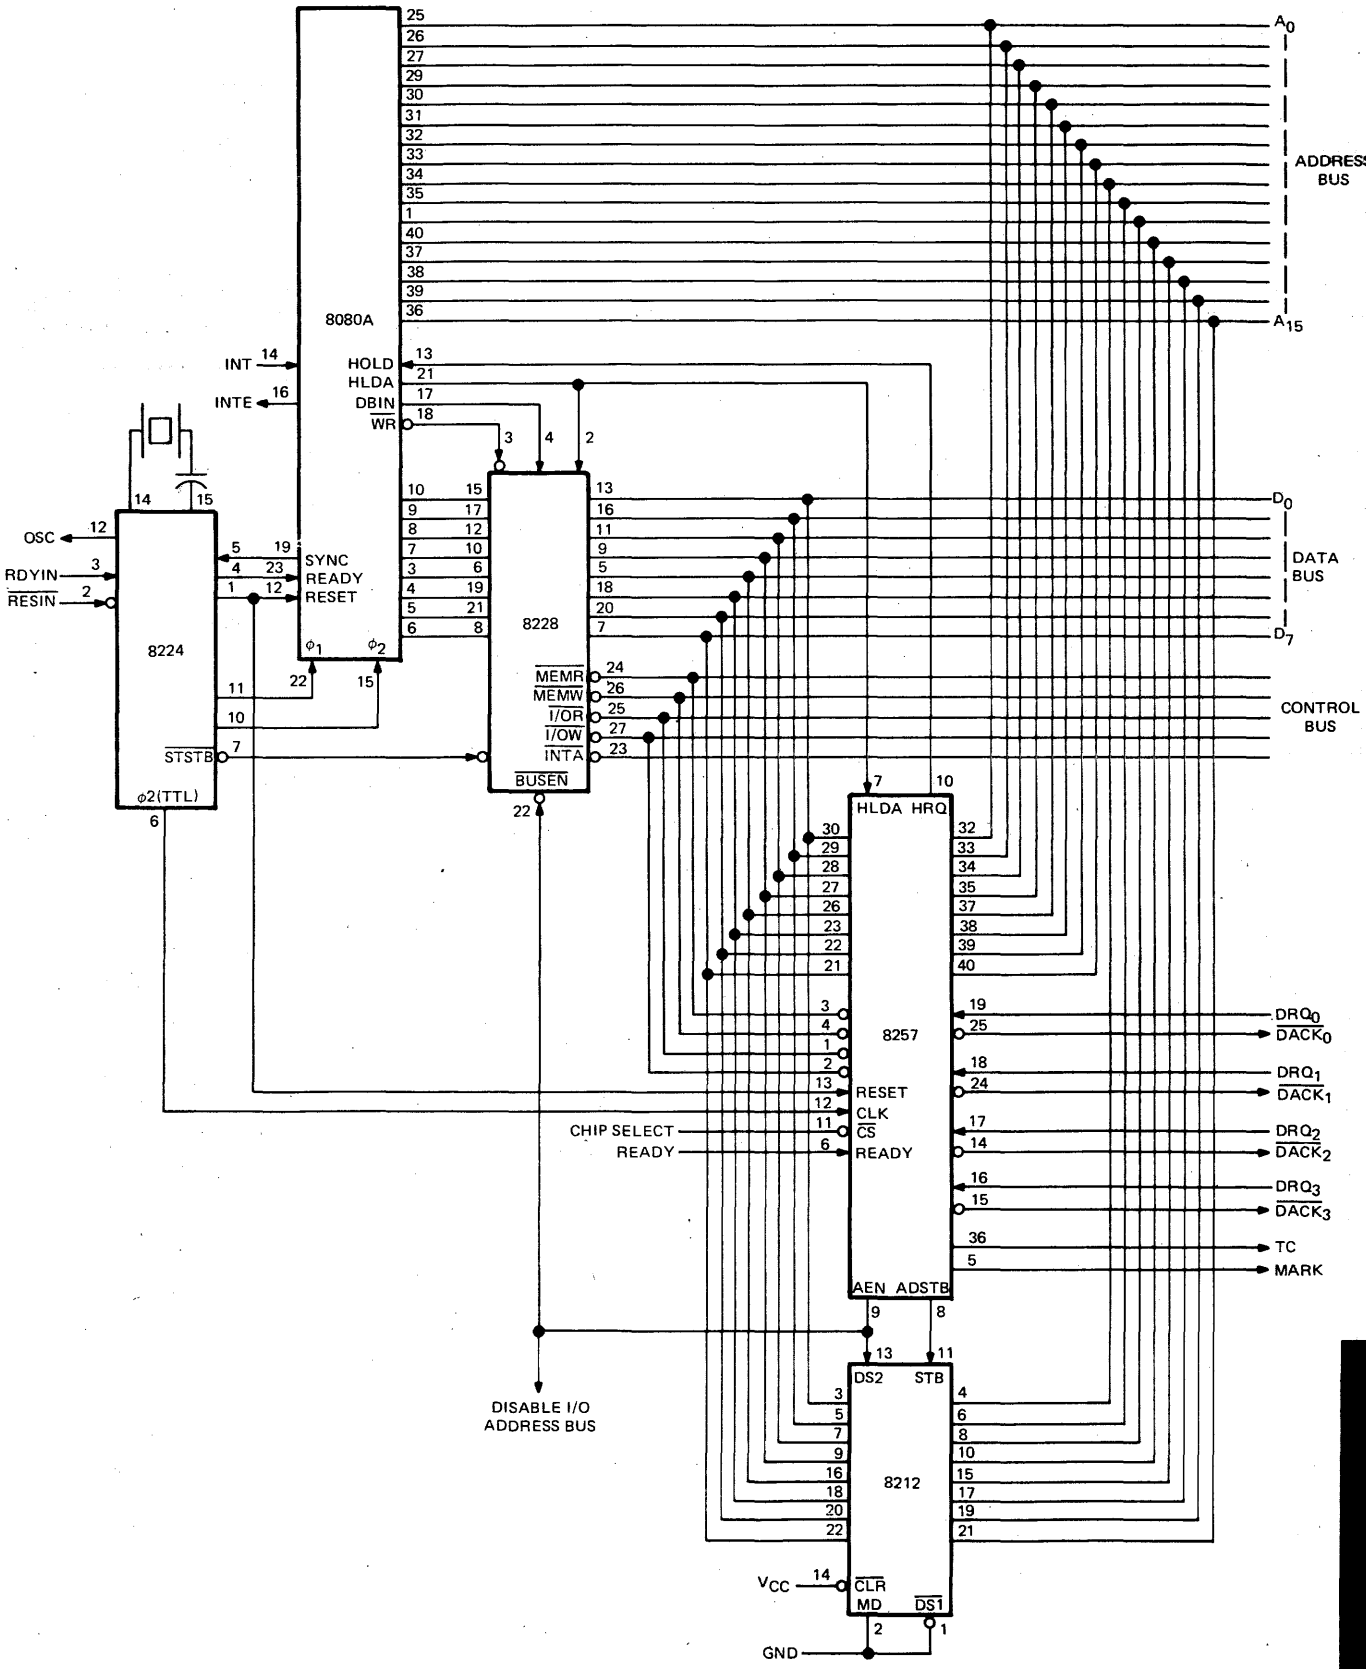


Internally the 8257 contains six different states (S0, S1, S2, S3, S4 and SW), the duration of each state is determined by the input clock. In the idle state, (S1), no DMA operation is being executed. A DMA cycle is started upon receipt of one or more DMA Requests (DRQ_n), then the 8257 enters the S0 state. During state S0 a Hold Request (HRQ) is sent to the 8080 and the 8257 waits in S0 until the 8080 issues a Hold Acknowledge (HLDA) back. During S0, DMA Requests are sampled and DMA priority is resolved (based upon either the fixed or priority scheme). After receipt of HLDA, the DMA Acknowledge line ($\overline{DACK}_n$) with the highest priority is driven low selecting that particular peripheral for the DMA cycle. The DMA Request line (DRQ_n) must remain high until either a DMA Acknowledge ($\overline{DACK}_n$) or both $\overline{DACK}_n$ and TC (Terminal Count) occur, indicating the end of a block or sector transfer (burst mode).

The DMA cycle consists of four internal states; S1, S2, S3 and S4. If the access time of the memory or I/O device is not fast enough to return a Ready command to the 8257 after it reaches state S3, then a Wait state is initiated (SW). One or more than one Wait state occurs until a Ready signal is received, and the 8257 is allowed to go into state S4. Either the extended write option or the DMA Verify mode may eliminate any Wait state.

If the 8257 should lose control of the system bus (i.e., HLDA goes low) then the current DMA cycle is completed, the device goes into the S1 state, and no more DMA cycles occur until the bus is reacquired. Ready setup time (t_{RS}), write setup time (t_{DW}), read data access time (t_{RD}) and HLDA setup time (t_{QS}) should all be carefully observed during the handshaking mode between the 8257 and the 8080.

During DMA write cycles, the I/O Read ($\overline{I/O\ R}$) output is generated at the beginning of state S2 and the Memory Write ($\overline{MEMW}$) output is generated at the beginning of S3. During DMA read cycles, the Memory Read ($\overline{MEMR}$) output is generated at the beginning of state S2 and the I/O Write ($\overline{I/O\ W}$) goes low at the beginning of state S3. No Read or Write control signals are generated during DMA verify cycles.



DMA OPERATION STATE DIAGRAM

Notes: ① HRQ is set if DRQ_n is active.
② HRQ is reset if DRQ_n is not active.

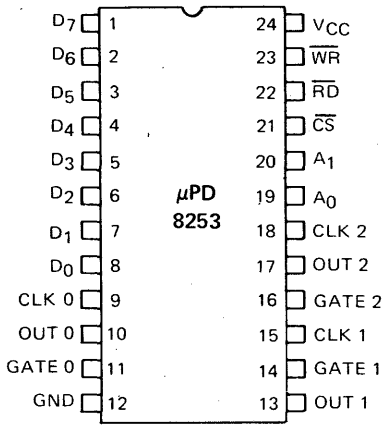
PROGRAMMABLE INTERVAL TIMER



DESCRIPTION

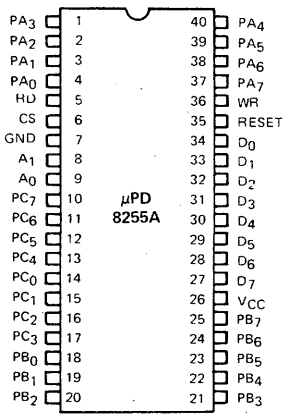
The NEC μPD8253 is a fully programmable, multi-mode, 16-bit counter/timer. It is designed as a general purpose device capable of interfacing directly to an 8080 microprocessor system as an array of I/O ports. The μPD8253 can generate accurate time delays under the control of system software. It contains three independent 16-bit counters which can be clocked at rates from DC to 2 MHz.

FEATURES

- Three Independent 16-Bit Counters
- DC to 2 MHz
- Programmable Counter Modes
- Count Binary or BCD
- Single +5V Supply
- 24 Pin Dual-In-Line Package
- +5V NMOS Technology

PIN CONFIGURATION

PROGRAMMABLE PERIPHERAL INTERFACE



DESCRIPTION

The NEC μPD8255A is a programmable peripheral interface device having 24 programmable I/O pins. It is directly compatible with the 8080 microprocessor system, and normally no extra logic is required to interface to the 8080A. The system software can individually program each of the 24 I/O pins into two groups of twelve for the three major modes of operation.

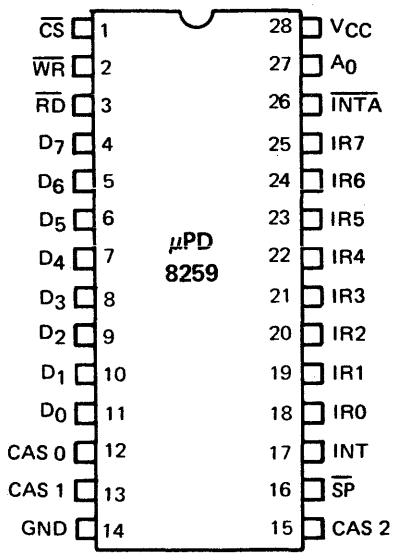
FEATURES

- Completely TTL Compatible
- Fully Compatible with NEC μP Families
- Direct Bit Set/Reset Capabilities Easing Control Application Interface
- 40 Pin Dual-In-Line Package
- Reduces System Package Count
- Capabilities to Drive Darlington Pairs

PIN CONFIGURATION

©IC MASTER 1978

PROGRAMMABLE INTERRUPT CONTROLLER



DESCRIPTION

The NEC μPD8259 is a programmable interrupt controller which can handle up to eight vectored priority interrupts in an 8080 microprocessor system. It can be cascaded to extend the vectored priority interrupt capability to 64 without extra circuitry. It is system software programmable with a selection of priority algorithms available which can be dynamically changed at any time.

FEATURES

- Eight Level Priority Controller
- Expandable to 64 Levels
- Programmable Interrupt Algorithms
- Individual Request Mask Capability
- Single +5V Supply
- Static Circuitry (No Clock)

PIN CONFIGURATION

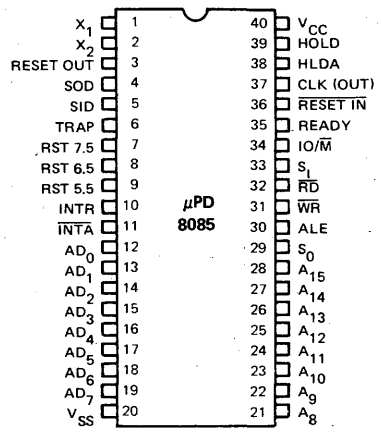
NEC microcomputers, inc.

PRELIMINARY

μPD8085

SINGLE CHIP 8-BIT N-CHANNEL MICROPROCESSOR



DESCRIPTION

The NEC μPD8085 is the next generation single chip 8-bit microprocessor. It provides full software compatibility with the 8080A but with an improved, higher system speed. The μPD8085's higher level of system integration allows the functions of the μPD8224 (clock generator) and the μPD8228 (system controller) to be incorporated into its design. Together with the μPD8155/8156 (2K RAM) and the μPD8355/8755 (16K ROM/EPROM) a minimum system can be configured using just three IC's. The DATA BUS of the μPD8085 multiplexes the 8-bit address bus and the 8-bit data bus to achieve greater system throughput. The μPD8155/8156 and the μPD8355/8755 memory products have on-chip address latches which provide direct interfacing to the μPD8085.

FEATURES

- Single +5V Supply
- 1.3 μs Instruction Cycle
- On-Chip System Controller
- 100% Software Compatibility with the μCOM-8 Family
- On-Chip Clock Generator (with External Crystal or RC Network)
- Four Vectored Interrupts (One is Non-Maskable)
- Serial In/Serial Out Port
- Decimal, Binary and Double Precision Arithmetic
- Direct Addressing Capability to 64K Bytes of Memory

PIN CONFIGURATION

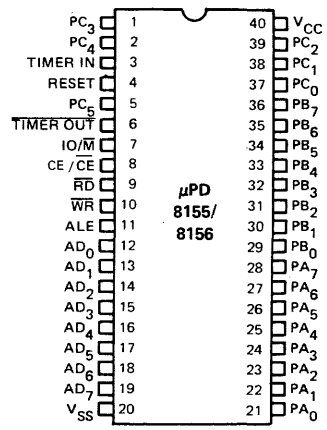
NEC microcomputers, inc.

PRELIMINARY

μPD8155

μPD8156

2048 BIT STATIC MOS RAM WITH I/O PORTS AND TIMER



DESCRIPTION

The NEC μPD8155 and μPD8156 2048-bit Static Random Access Memories are organized as 256 x 8 and are fully compatible with the μPD8085 microprocessor system. Three I/O pins allow programmable status and handshaking capabilities with the processor. The on-chip 14 bit counter timer is fully programmable by the system software.

FEATURES

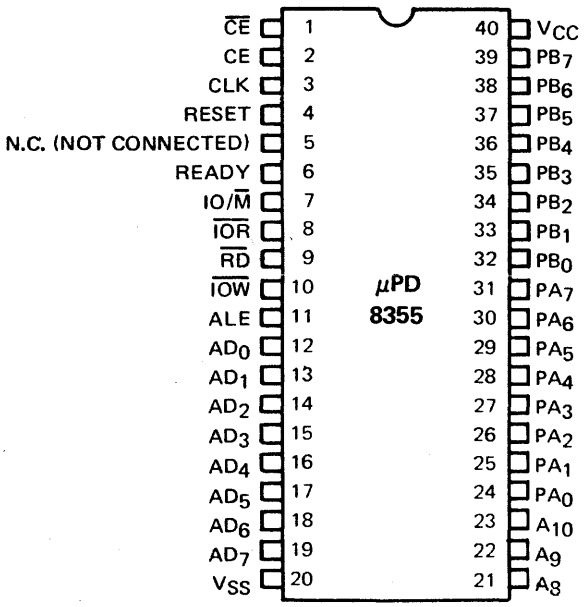
- 256 Words x 8 Bits Organization
- 400 ns Access Time (No Wait States Required)
- Multiplexed Address and Data Bus
- Programmable 14 Bit Binary Counter/Timer
- 1 Programmable 6 Bit I/O Port
- 2 Programmable 8 Bit I/O Ports

PIN CONFIGURATION

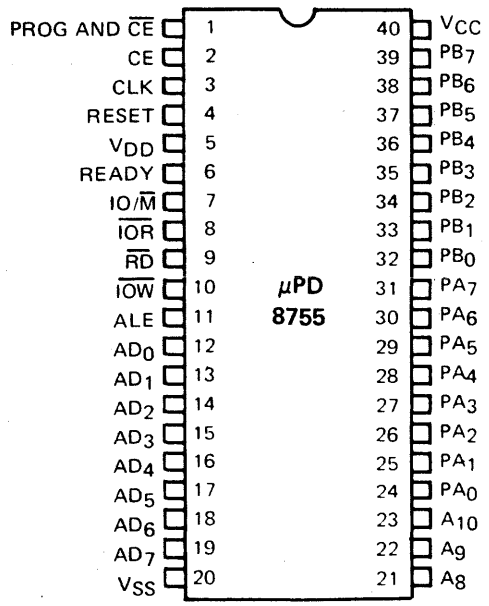
©IC MASTER 1978

μPD8355
μPD8755

16,384 BIT ROM WITH I/O / 16,384 BIT EPROM WITH I/O



DESCRIPTION



The NEC μPD8355 is a 16,384 bit Read Only Memory with I/O organized as 2048 words x 8 bits. The μPD8755 is a 16,384 bit erasable and electrically programmable Read Only Memory. Access time for both devices is 400 ns so no wait state are required in the processor. There are two separately programmable, 8 bit wide I/O ports for interfacing to the processor.

FEATURES

- 2048 Words x 8 Bits
- Single +5V Power Supply
- Internal Address Latch
- 2 General Purpose 8 Bit I/O Ports
- Multiplexed Address and Data Bus
- Direct Compatibility with μPD8085 and μPD8048

PIN CONFIGURATIONS

©IC MASTER 1978

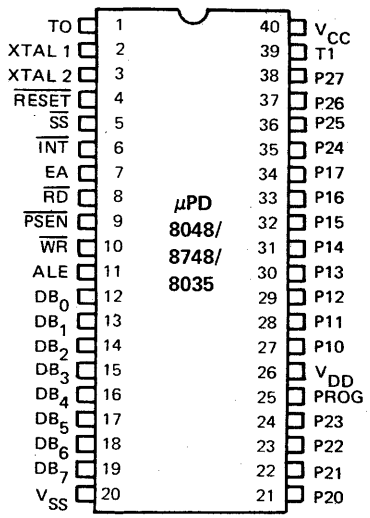
μPD8048
μPD8748
μPD8035

SINGLE COMPONENT 8-BIT MICROCOMPUTER

DESCRIPTION

The NEC μPD8048/8748/8035 are complete, single-chip, NMOS microcomputers requiring only a single +5V power supply. There are three interchangeable microcomputers in this family to allow the user maximum freedom in systems implementation. In addition, if system expansion is necessary, the μPD8048/8748/8035 are fully compatible with NEC's family of 8080A peripherals including memory devices.

The on-chip features of the μPD8048 include 1K x 8 bits of Read Only Memory for firm program storage, 64 x 8 bits of Random Access Memory which can be used as a scratch pad, 27 I/O lines, an 8-bit counter/timer and clock, oscillator and clock driver circuitry requiring only an off-the-chip crystal.



The μPD8035 is functionally and pin-for-pin compatible with the μPD8048 but without the 1K x 8 bit ROM, which is intended for use with external memory.

The μPD8748 is also fully compatible with both the μPD8048 and μPD8035. In this device the 1K x 8 bit ROM has been replaced with a 1K x 8 bit erasable, electrically programmable ROM to provide the user with the flexibility of changing the program memory contents.

FEATURES

- 8 Bit Parallel Processor, ROM, RAM, I/O in Single Package
- Interchangeable ROM and EPROM Versions
- Single +5V Supply
- 2.5 μsec and 5.0 μsec Cycle Versions
  All Instructions 1 or 2 Cycles
- Over 90 Instructions: 70% Single Byte
  None Over Two Bytes
- 1K x 8 ROM/EPROM, 64 x 8 RAM,
  27 I/O Lines
- Programmable Counter/Timer
- Easily Expandable Memory and I/O
- Single Level Interrupt
- Compatible with μCOM-8 Series Peripherals

PIN CONFIGURATION

©IC MASTER 1978

μPB2901 4-BIT MICROPROCESSOR SLICE

DESCRIPTION

The NEC μPB2901 is a four-bit microprocessor slice, with an expandable bus structure extending interface capabilities to all other members of the μPB2900 series family. The internal functions of the μPB2901 include an eight-function ALU, sixteen addressable registers using separate read and read/write address busses, an auxiliary register and shifting logic.

Other members of the μPB2900 series family are:

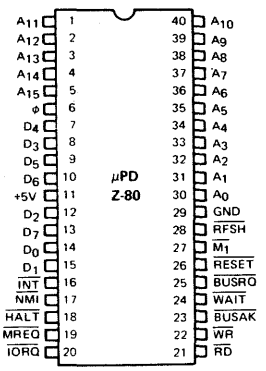
μPB2902 . . . . . 4-Bit Carry Look-Ahead
μPB2909 . . . . . 4-Bit Microprogram Sequencer
μPB2911 . . . . . 4-Bit Microprogram Sequencer
μPB2905 . . . . . OC Bus Transceiver with Tri-State Receiver
μPB2906 . . . . . OC Bus Transceiver with Parity
μPB2907 . . . . . OC Bus Transceiver with Parity and Tri-State Receiver
μPB2915 . . . . . Tri-State Bus Transceiver with Tri-State Receiver
μPB2916 . . . . . Tri-State Transceiver with Parity
μPB2917 . . . . . Tri-State Bus Receiver with Parity and Tri-State Receiver
μPB2918 . . . . . 4-Bit D-Register with Standard and Tri-State Output

FEATURES

- 4-Bit CPU Slice
- Standard 40 Pin Dual-In-Line Package
- Register-to-Register, Read/Modify/Write Time of 150 ns (Worst Case)
- 8 Function ALU
- 16 Working Registers
- Auxiliary Register
- Shifting Logic

SINGLE CHIP 8-BIT MICROPROCESSOR

DESCRIPTION



The NEC μPDZ-80 is a third generation, N-Channel microprocessor providing many advancements over second generation microprocessors. The μPDZ-80 processor offers a savings in systems throughput and reduced memory requirements through its expanded 158 software instruction set, while maintaining software compatibility with the 8080A. The expanded instruction set allows for a higher level of system operation by providing for memory-to-memory block transfers, bit manipulation and sampling in any register or memory location, enhanced 16-bit and BCD arithmetic, new I/O features such as I/O block transfers and expanded addressing modes (indexed and relative).

The μPDZ-80 provides all the control and refresh control signals for interfacing with most 4K static or dynamic memories. Only an external address decoder is needed for the static memories' chip selects. In addition, seventeen registers and 208 bits of programmer usable Read/Write memory on-chip all contribute to the power and versatility of this device.

FEATURES

- 158 Instructions (Including all 78 Instructions of the 8080A)
- 17 Internal Register
- Three Modes of Fast Interrupt Response and a Non-Maskable Interrupt
- Direct Interface with Standard Speed Dynamic or Static Memories
- 1.6 μs Instruction Execution Time
- Single +5V Supply
- Single-Phase TTL Clock
- TTL Compatible Tri-State Address and Data Busses

PIN CONFIGURATION

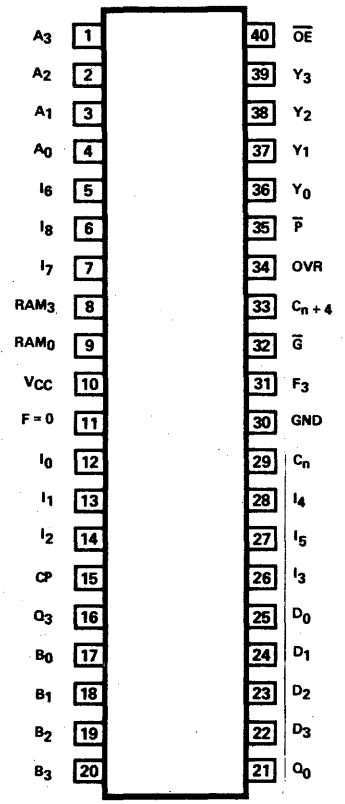
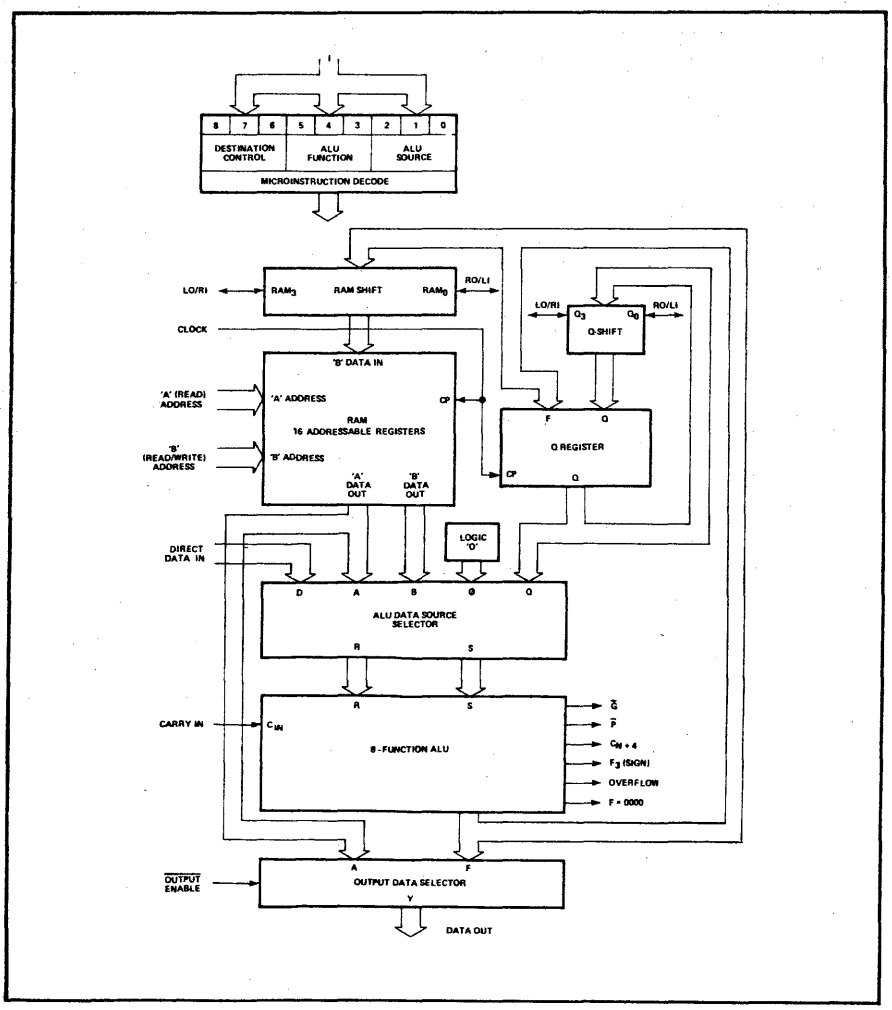
DESCRIPTION

The 4-bit bipolar microprocessor slice is designed as a high-speed cascadable element intended for use in CPUs, peripheral controllers, programmable microprocessors and numerous other applications. The microinstruction flexibility of the 2901-1 will allow efficient emulation of almost any digital computing machine.



The device, as shown in the block diagram below, consists of a 16-word by 4-bit 2-port RAM, a high-speed ALU, and the associated shifting, decoding and multiplexing circuitry. The 9-bit microinstruction word is organized into 3 groups of 3 bits each and selects the ALU source operands, the ALU function, and the ALU destination register. The microprocessor is cascadable with full look-ahead or with ripple carry, has three-state outputs, and provides various status flag outputs from the ALU. Advanced low-power Schottky processing is used to fabricate this 40-lead LSI chip.

FEATURES



- **80ns cycle time**
- **2-address architecture**
  Independent simultaneous access to 2 working registers saves machine cycles
- **8-function ALU**
  Performs addition, 2 subtraction operations, and 5 logic functions on 2 source operands
- **Flexible data source selection**
  ALU data is selected from 5 source ports for a total of 203 source operand pairs for every ALU function
- **Left/right shift independent of ALU**
  Add and shift operations take only 1 cycle
- **4 status flags**
  Carry, overflow, zero, and negative
- **Expandable**
  Connect any number of 2901-1's together for longer word lengths
- **Microprogrammable**
  3 groups of 3 bits each for source operand, ALU function, and destination control

PIN DESIGNATION

PIN	SYMBOL	NAME AND FUNCTION	TYPE
1-4	A_0-A_3	**A Address** The 4 address inputs to the register stack used to select 1 register whose contents are displayed through the A port. A_0 is the LSB.	Active high
17-20	B_0-B_3	**B Address** The 4 address inputs to the register stack used to select 1 register whose contents are displayed through the B port and into which new data can be written when the clock goes LOW. B_0 is the LSB.	Active high
12-14, 26-28, 5-7	I_0-I_8	**Instruction Control** The 9 instruction control lines to the 2901-1 used to determined what data sources will be applied to the ALU (I_{012}), what function the ALU will perform (I_{345}), and what data is to be deposited in the Q register or the register stack (I_{678}).	Active high
8 16	RAM_3 Q_3	**Shift Line** A shift line at the MSB of the Q register (Q_3) and the register stack (RAM_3). Electrically these lines are three-state outputs connected to TTL inputs internal to the 2901-1. When the destination code on I_{678} indicates a left (up) shift (octal 6 or 7) the three-state outputs are enabled and the MSB of the Q register is available on the Q_3 and the MSB of the ALU output is available on the RAM_3 pin. Otherwise, the three-state outputs are off (high-impedance) and the pins are electrically LS-TTL inputs. When the destination code calls for a right (down) shift, the pins are used as the data inputs to the MSB of the Q register (octal 4) and RAM (octal 4 or 5).	Three-state Active high
9 21	RAM_0 Q_0	**Shift Line** Shift lines similar to Q_3 and RAM_3, at the LSB of the Q register and RAM. These pins are tied to the Q_3 and RAM_3 pins of the adjacent device and are used to transfer data between devices for left and right shifts of the Q register and ALU data.	Active high
22-25	D_0-D_3	**Direct Data Inputs** A 4-bit data field which may be selected as one of the ALU data sources for entering data into the 2901-1. D_0 is the LSB.	Active high
36-39	Y_0-Y_3	**Data Out** The 4 data outputs of the 2901-1. These are three-state output lines. When enabled, they display either the 4 outputs of the ALU or the data on the A port of the register stack, as determined by the destination code I_{678}. Y_0 is the LSB.	Three-state Active high
40	$\overline{OE}$	**Output Enable** When $\overline{OE}$ is High, the Y outputs are disabled; when $\overline{OE}$ is Low, the Y outputs are active (high or low).	Active low
32, 35	$\overline{G}$, $\overline{P}$	**Carry Generate, Propagate** The carry generate and propagate outputs of the 2901-1. These signals are used with the N74S182 for carry-lookahead. See Table 7 for the logic equations.	Active low
34	OVR	**Overflow** This pin is logically the Exclusive-OR of the carry-in and carry-out of the MSB of the ALU. At the most significant end of the word, this pin indicates that the result of an arithmetic two's complement operation has overflowed into the sign-bit. See Table 7 for logic equation.	Active high
11	F = 0	**F = 0** This is an open collector output which goes High (off) if the data on the 4 ALU outputs F_{0-3} are all low. In positive logic, it indicates the result of an ALU operation is zero.	Active high
29	C_n	**Carry In**	Active high
33	C_{n+4}	**Carry Out** (See Table 7 for logic equations.)	Active high
15	CP	**Clock** The Q register and register stack outputs change on the clock Low-to-High transition. The clock Low time is internally the write enable to the 16X4 RAM which comprises the "master" latches of the register stack. While the clock is Low, the "slave" latches on the RAM outputs are closed, storing the data previously on the RAM outputs. This allows synchronous master-slave operation of the register stack.	Active high

SYSTEM DESCRIPTION

A detailed block diagram of the bipolar microprogrammable microprocessor structure is shown in Figure 1. The circuit is a 4-bit slice cascadable to any number of bits. Therefore, all data paths within the circuit are 4 bits wide. The two key elements in the Figure 1 block diagram are the 16-word by 4-bit 2-port RAM and the high-speed ALU.

Data in any of the 16 words of the Random Access Memory (RAM) can be read from the A port of the RAM as controlled by the 4-bit A address field input. Likewise, data in any of the 16 words of the RAM as defined by the B address field input can be simultaneously read from the B port of the RAM. The same code can be applied to the A select field and B select field in which case the identical file data will appear at both the RAM A port and B port outputs simultaneously.

When enabled by the RAM write enable (RAM EN), new data is always written into the file (word) defined by the B address field of the RAM. The RAM data input field is driven by a 3-input multiplexer. This configuration is used to shift the ALU output data (F) if desired. This 3-input multiplexer scheme allows the data to be shifted up (left) 1 bit position, shifted down (right) 1 bit position, or not shifted in either direction.

The RAM A port data outputs and RAM B port data outputs drive separate 4-bit latches. These latches hold the RAM data while the clock input is low. This eliminates any possible race conditions that could occur while new data is being written into the RAM.

The high-speed Arithmetic Logic Unit (ALU) can perform 3 binary arithmetic and 5 logic operations on the two 4-bit input words R and S. The R input field is driven from a 2-input multiplexer, while the S input field is driven from a 3-input multiplexer. Both multiplexers also have an inhibit capability; that is, no data is passed. This is equivalent to a "zero" source operand.

Referring to Figure 1, the ALU R-input multiplexer has the RAM A port and the direct data inputs (D) connected as inputs. Likewise, the ALU S input multiplexer has the RAM A port, the RAM B port and the Q register connected as inputs.

This multiplexer scheme gives the capability of selecting various pairs of the A, B, D, Q and "0" inputs as source operands to the ALU. These 5 inputs, when taken 2 at a time, result in 10 possible combinations of source operand pairs. These combinations include AB, AD, AQ, A0, BD, BQ, B0, DQ, D0 and Q0. It is apparent that AD, AQ and A0 are somewhat redundant with BD, BQ and B0 in that if the A address and B address are the same, the identical function results. Thus, there are only 7 completely non-redundant source operand pairs for the ALU. The 2901-1 microprocessor implements 8 of these pairs. The microinstruction inputs used to select the ALU source operands are the I_0, I_1, and I_2 inputs. The definition of I_0, I_1, and I_2 for the 8 source operand combinations are as shown in Table 1. Also shown is the octal code for each selection.

DETAILED 2901-1 BLOCK DIAGRAM

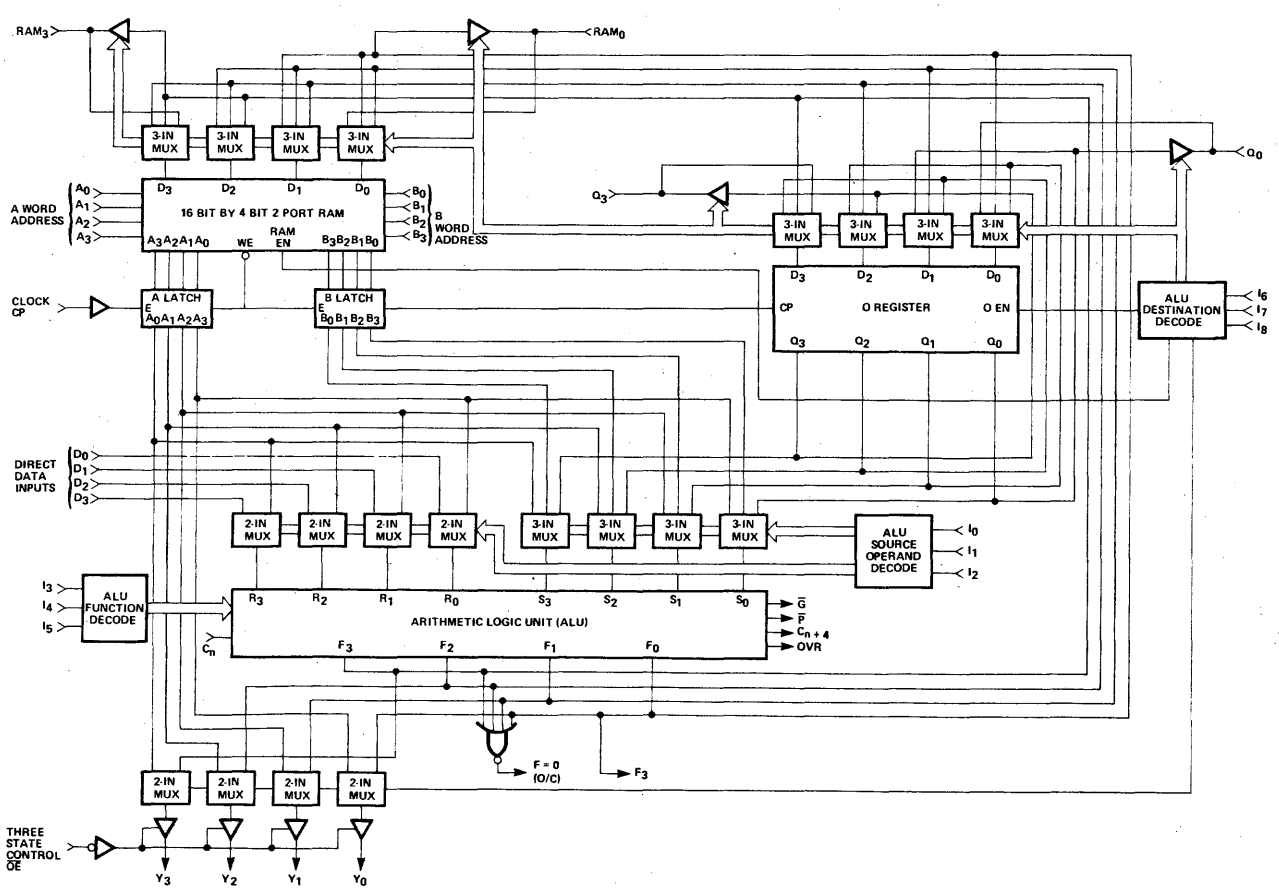

Figure 1

MICRO CODE				ALU SOURCE OPERANDS	
I_2	I_1	I_0	Octal Code	R	S
L	L	L	0	A	Q
L	L	H	1	A	B
L	H	L	2	0	Q
L	H	H	3	0	B
H	L	L	4	0	A
H	L	H	5	D	A
H	H	L	6	D	Q
H	H	H	7	D	0

Table 1 ALU SOURCE OPERAND CONTROL

The 2 source operands not fully described as yet are the D input and Q input. The D input is the 4-bit wide direct data field input. This port is used to insert all data into the working registers inside the device. Likewise, this input can be used in the ALU to modify any of the internal data files. The Q register is a separate 4-bit file intended primarily for multiplication and division routines but it can also be used as an accumulator or holding register for some applications.

The ALU itself is a high-speed arithmetic/logic operator capable of performing 3 binary arithmetic and 5 logic functions. The I_3, I_4, and I_5 microinstruction inputs are used to select the ALU function. The definition of these inputs is shown in Table 2. The octal code is also shown for reference. The normal technique for cascading the ALU of several devices is in a look-ahead carry mode. Carry generate, G, and carry propagate, P, are outputs of the device for use with a carry-look-ahead-generator such as the N74S182. A carry-out, C_{n+4}, is also generated and is available as an output for use as the carry flag in a status register. Both carry-in (C_n) and carry-out (C_{n+4}) are active high.

MICRO CODE				ALU	
I_5	I_4	I_3	Octal Code	Function	Symbol
L	L	L	0	R Plus S	R + S
L	L	H	1	S Minus R	S - R
L	H	L	2	R Minus S	R - S
L	H	H	3	R OR S	R $\vee$ S
H	L	L	4	R AND S	R $\wedge$ S
H	L	H	5	$\overline{R}$ AND S	$\overline{R} \wedge S$
H	H	L	6	R EX-OR S	R $\forall$ S
H	H	H	7	R EX-NOR S	$\overline{R \forall S}$

Table 2 ALU FUNCTION CONTROL

The ALU has three other status-oriented outputs. These are F_3, F = 0, and overflow (OVR). The F_3 output is the most significant (sign) bit of the ALU and can be used to determine positive or negative results without enabling the three-state data outputs. F_3 is non-inverted with respect to the sign bit output Y_3. The F = 0 output is used for zero detect. It is an open-collector output and can be wire OR'ed between microprocessor slices. F = 0 is high when all F outputs are low. The overflow output (OVR) is used to flag arithmetic operations that exceed the available two's complement number range. The overflow output (OVR) is high when overflow exists. That is, when C_{n+3} and C_{n+4} are not the same polarity.

The ALU data output is routed to several destinations. It can be a data output of the device and it can also be stored in the RAM or the Q register. Eight possible combinations of ALU destination functions are available as defined by the I_6, I_7, and I_8 microinstructon inputs. These combinations are shown in Table 3.

MICRO CODE				RAM FUNCTION		Q REGISTER FUNCTION		Y OUTPUT	RAM SHIFTER		Q SHIFTER	
I_8	I_7	I_6	Octal Code	Shift	Load	Shift	Load		RAM_0 LO/RI	RAM_3 LI/RO	Q_0 LO/RI	Q_3 LI/RO
L	L	L	0	X	None	None	F → Q	F	X	X	X	X
L	L	H	1	X	None	X	None	F	X	X	X	X
L	H	L	2	None	F → B	X	None	A	X	X	X	X
L	H	H	3	None	F → B	X	None	F	X	X	X	X
H	L	L	4	Right (Down)	F/2 → B	Right (Down)	Q/2 → Q	F	F_0	IN_3	Q_0	IN_3
H	L	H	5	Right (Down)	F/2 → B	X	None	F	F_0	IN_3	Q_0	X
H	H	L	6	Left (Up)	2F → B	Left (Up)	2Q → Q	F	IN_0	F_3	IN_0	Q_3
H	H	H	7	Left (Up)	2F → B	X	None	F	IN_0	F_3	X	Q_3

X = Don't care. Electrically, the shift pin is a TTL input internally connected to a three-state output which is in the high-impedance state.

Table 3 ALU DESTINATION CONTROL

The 4-bit data output field (Y) features three-state outputs and can be directly bus organized. An output control ($\overline{OE}$) is used to enable the three-state outputs. When $\overline{OE}$ is high, the Y outputs are in the high-impedance state.

A 2-input multiplexer is also used at the data output such that either the A port of the RAM or the ALU outputs (F) are selected at the device Y outputs. This selection is controlled by the I_6, I_7, and I_8 microinstruction inputs. Refer to Table 3 for the selected output for each microinstruction code combination.

As was discussed previously, the RAM inputs are driven from a 3-input multiplexer. This allows the ALU outputs to be entered non-shifted, shifted up (left) one position (X2) or shifted down (right) one position (÷2). The shifter has 2 ports; one is labeled RAM_0 and the other is labeled RAM_3. Both of these ports consist of a buffer-driver with a three-state output and an input to the multiplexer. Thus, in the shift up mode, the RAM_3 buffer is enabled and the RAM_0 multiplexer input is enabled. Likewise, in the shift down mode, the RAM_0 buffer and RAM_3 input are enabled. In the no-shift mode, both buffers are in the high-impedance state and the multiplexer inputs are not selected. This shifter is controlled from the I_6, I_7, and I_8 microinstruction inputs as defined in Table 3.

Similarly, the Q register is driven from a 3-input multiplexer. In the no-shift mode, the multiplexer enters the ALU data into the Q register. In either the shift-up or shift-down mode, the multiplexer selects the Q register data appropriately shifted up or down. The Q shifter also has 2 ports; one is labeled Q_0 and the other is Q_3. The operation of these 2 ports is similar to the RAM shifter and is also controlled from I_6, I_7, and I_8 as shown in Table 3.

The clock input to the 2901-1 controls the RAM, the Q register, and the A and B data latches. When enabled, data is clocked into the Q register on the low-to-high transition of the clock. When the clock input is high, the A and B latches are open and will pass whatever data is present at the RAM outputs. When the clock input is low, the latches are closed and will retain the last data entered. If the RAM-EN is enabled, new data will be written into the RAM file (word) defined by the B address field when the clock input is low.

©IC MASTER 1978

SOURCE OPERANDS AND ALU FUNCTIONS

There are eight source operand pairs available to the ALU as selected by the I_0, I_1, and I_2 instruction inputs. The ALU can perform eight functions; five logic and three arithmetic. The I_3, I_4, and I_5 instruction inputs control this function selection. The carry input, C_n, also affects the ALU results when in the arithmetic mode. The C_n input has no effect in the logic mode. When I_0 through I_5 and C_n are viewed together, the matrix of Table 4 results. This matrix fully defines the ALU/source operand function for each state.

The ALU functions can also be examined on a "task" basis, i.e., add, subtract, AND, OR, etc. In the arithmetic mode, the carry will affect the function performed while in the logic mode, the carry will have no bearing on the ALU output. Table 5 defines the various logic operations that the 2901-1 can perform and Table 6 shows the arithmetic functions of the device. Both carry-in low (C_n = 0) and carry-in high (C_n = 1) are defined in these operations.

LOGIC FUNCTIONS FOR $\overline{G}$, $\overline{P}$, C_{n+4}, AND OVR

The four signals $\overline{G}$, $\overline{P}$, C_{n+4}, and OVR are designed to indicate carry and overflow conditions when the 2901-1 is in the add or subtract mode. Table 7 indicates the logic equations for these four signals for each of the eight ALU functions. The R and S inputs are the two inputs selected according to Table 1.

I_{543}	FUNCTION	$\overline{P}$	$\overline{G}$	C_{n+4}	OVR
0	R + S	$\overline{P_3P_2P_1P_0}$	$\overline{G_3 + P_3G_2 + P_3P_2G_1 + P_3P_2P_1G_0}$	C_4	$C_3 \forall C_4$
1	S - R	← Same as R+S equations, but substitute $\overline{R}_i$ for R_i in definitions →			
2	R - S	← Same as R+S equations, but substitute $\overline{S}_i$ for S_i in definitions →			
3-7	All logic operations	High	Low	High	High

NOTES

1. LO/RI and RO/LI are three-state outputs internally connected to TTL inputs. Input characteristics are measured with I_{678} in a state such that the three-state output is OFF.
2. Not more than 1 output should be shorted at a time. Duration of the short-circuit test should not exceed 1 second.

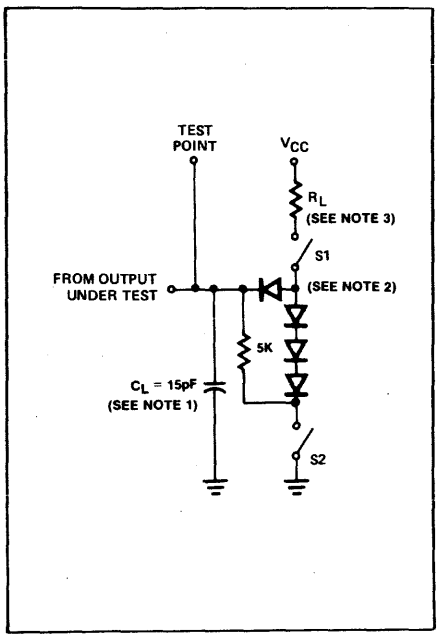
t_{SS}	$RAM_{3,0}$, input setup time	30	20		ns
	$Q_{3,0}$	15	10		

NOTES



1. Setup and hold times are defined relative to the clock low-to-high edge. Inputs must be steady at all times from the setup time prior to the clock until the hold after the clock. The setup times allow sufficient time to perform the correct operation on the correct operation on the correct data so that the correct ALU data can be written into one of the registers.
2. If the B address is used as a source operand, allow for the A, B source setup time; if it is used only for the destination address, use the B dest. setup time.
3. Where 2 numbers are shown, both must be met.
4. t_{CL} is the clock low time.

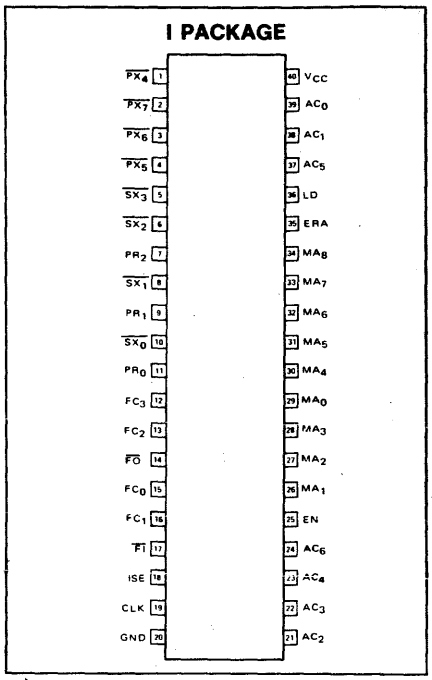
S/N3001-I

DESCRIPTION

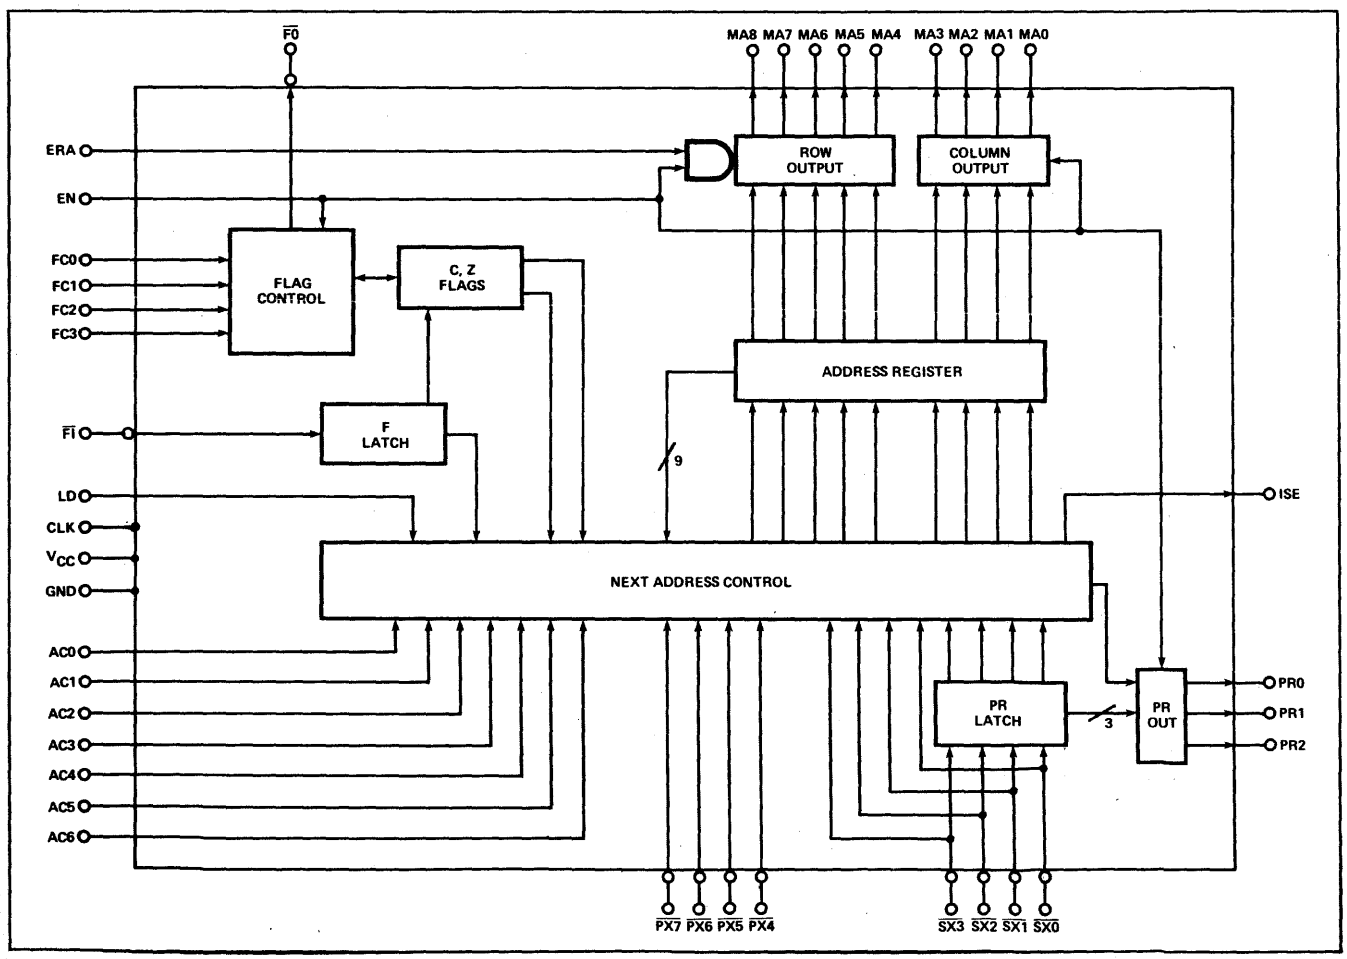
The S/N3001 MCU is 1 element of a bipolar microcomputer set. When used with the S/N3002, 54/74S182, ROM or PROM memory, a powerful microprogrammed computer can be implemented.

The 3001 MCU controls the fetch sequence of microinstructions from the microprogram memory. Functions performed by the 3001 include:



- Maintenance of microprogram address register
- Selection of next microinstruction address
- Decoding and testing of data supplied via several input buses
- Saving and testing of carry output data from the central processing (CP) array
- Control of carry/shift input data to the CP array
- Control of microprogram interrupts

FEATURES



- **Schottky TTL process**
- **45ns cycle time (typ.)**
- **Direct addressing of standard bipolar PROM or ROM**
- **512 microinstruction addressability**
- **Advanced organization:**
  - **9-bit microprogram address register and bus organized to address memory by row and column**
  - **4-bit program latch**
  - **2-flag registers**
- **11 address control functions:**
  - **3 jump and test latch function**
  - **16 way jump and test instruction**
- **8 flag control functions:**
  - **4 flag input functions**
  - **4 flag output functions**

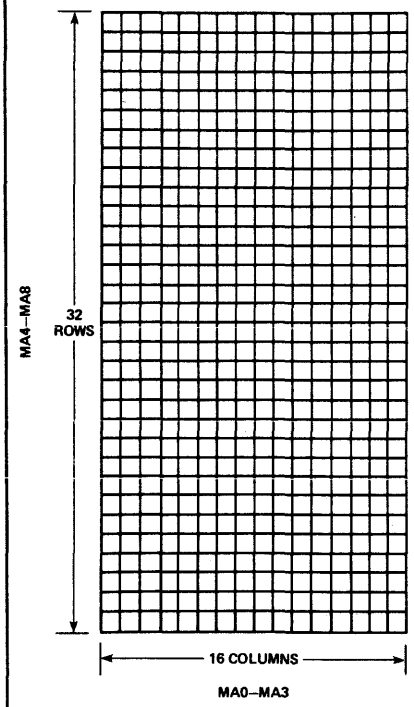
PIN DESIGNATION

PIN	SYMBOL	NAME AND FUNCTION	TYPE
1-4	$\overline{PX_4}$-$\overline{PX_7}$	Primary Instruction Bus Inputs Data on the primary instruction bus is tested by the JPX function to determine the next microprogram address.	Active low
5,6,8,10	$\overline{SX_0}$-$\overline{SX_3}$	Secondary Instruction Bus Inputs Data on the secondary instruction bus is synchronously loaded into the PR-latch while the data on the PX-bus is being tested (JPX). During a subsequent cycle, the contents of the PR-latch may be tested by the JPR, JLL, or JRL functions to determine the next microprogram address.	Active low
7,9,11	PR_0-PR_2	PR-Latch Outputs The PR-latch outputs (SX_0-SX_2) are synchronously enabled by the JCE function. They can be used to modify microinstructions at the outputs of the microprogram memory or to provide additional control lines.	Open Collecto
12,13 15,16	FC_0-FC_3	Flag Logic Control Inputs The flat logic control inputs are used to cross-switch the flags (C and Z) with the flag logic input (FI) and the flag logic output (FO).	Active high
14	$\overline{FO}$	Flag Logic Output The outputs of the flags (C and Z) are multiplexed internally to form the common flag logic output. The output may also be forced to a logical 0 or logical 1.	Active low Three-state
17	$\overline{FI}$	Flag Logic Input The flag logic input is demultiplexed internally and applied to the inputs of the flags (C and Z). Note: The flag input data is saved in the F-latch when the clock input (CLK) is low.	Active low
18	ISE	Interrupt Strobe Enable Output The interrupt strobe enable output goes to logical 1 when one of the JZR functions are selected (see Functional Description). It can be used to provide the strobe signal required by interrupt circuits.	Active high
19	CLK	Clock Input	
20	GND	Ground	
21-24 37-39	AC_0-AC_6	Next Address Control Function Inputs All jump functions are selected by these control lines.	Active high
25	EN	Enable Input When in the high state, the enable input enables the microprogram address, PR-latch and flag outputs.	
26-29	MA_0-MA_3	Microprogram Column Address Outputs	Three-state
30-34	MA_4-MA_8	Microprogram Row Address Outputs	Three-state
35	ERA	Enable Row Address Input When in the low state, the enable row address input independently disables the microprogram row address outputs. It can be used to facilitate the implementation of priority interrupt systems.	Active high
36	LD	Microprogram Address Load Input When the active high state, the microprogram address load input inhibits all jump functions and synchronously loads the data on the instruction buses into the microprogram address register. However, it does not inhibit the operation of the PR-latch or the generation of the interrupt strobe enable.	Active high
40	V_{CC}	+5 Volt supply	

THEORY OF OPERATION



The MCU controls the sequence of microinstructions in the microprogram memory. The MCU simultaneously controls 2 flip-flops (C, Z) which are interactive with the carry-in and carry-out logic of an array of CPEs.

The functional control of the MCU provides both unconditional jumps to new memory locations and jumps which are dependent on the state of MCU flags or the state of the "PR" latch. Each instruction has a "jump set" associated with it. This "jump set" is the total group of memory locations which can be addressed by that instruction.

The MCU utilizes a two-dimensional addressing scheme in the microprogram memory. Microprogram memory is organized as 32 rows and 16 columns for a total of 512 words. Word length is variable according to application. Address is accomplished by a 9-bit address organized as a 5-bit row and 4-bit column address.

©IC MASTER 1978

ADDRESSING ORGANIZATION

FUNCTIONAL DESCRIPTION

The following is a description of each of the eleven address control functions. The symbols shown below are used to specify row and column addresses.

MNEMONIC	FUNCTION
row_n	5-bit next row address where n is the decimal row address.
col_n	4-bit next column address where n is the decimal column address.

Unconditional Address Control (Jump) Functions

The jump functions use the current microprogram address (i.e., the contents of the microprogram address register prior to the rising edge of the clock) and several bits from the address control inputs (AC0-AC6) to generate the next microprogram address.

Flag Conditional Address Control (Jump Test) Functions

The jump/test flag functions use the current microprogram address, the contents of the selected flag or latch, and several bits from the address control function to generate the next microprogram address.

JUMP FUNCTION TABLE

MNEMONIC	NAME AND FUNCTION
JCC	Jump in current column. AC_0-AC_4 are used to select 1 of 32 row addresses in the current column, specified by MA_0-MA_3, as the next address.
JZR	Jump to zero row. AC_0-AC_3 are used to select 1 of 16 column addresses in row_0, as the next address.
JCR	Jump in current row. AC_0-AC_3 are used to select 1 of 16 addresses in the current row, specified by MA_4-MA_8, as the next address.
JCE	Jump in current column/row group and enable PR-latch outputs. AC_0-AC_2 are used to select 1 of 8 row addresses in the current row group, specified by MA_7-MA_8, as the next row address. The current column is specified by MA_0-MA_3. The PR-latch outputs are asynchronously enabled.

JUMP/TEST FUNCTION TABLE

MNEMONIC	NAME AND FUNCTION
JFL	Jump/test F-latch. AC_0-AC_3 are used to select 1 of 16 row addresses in the current row group, specified by MA_8, as the next row address. If the current column group, specified by MA_3, is col_0-col_7, the F-latch is used to select col_2 or col_3 as the next column address. If MA_3 specifies column group col_8-col_{15}, the F-latch is used to select col_{10} or col_{11} as the next column address.
JCF	Jump/test C-flag. AC_0-AC_2 are used to select 1 of 8 row addresses in the current row group, specified by MA_7 and MA_8, as the next row address. If the current column group specified by MA_3 is col_0-col_7, the C-flag is used to select col_2 or col_3 as the next column address. If MA_3 specifies column group col_8-col_{15}, the C-flag is used to select col_{10} or col_{11} as the next column address.
JZF	Jump/test Z-flag. Identical to the JCF function described above, except that the Z-flag, rather than the C-flag, is used to select the next column address.
JPR	Jump/test PR-latch. AC_0-AC_2 are used to select 1 of 8 row addresses in the current row group, specified by MA_7 and MA_8, as the next row address. The 4 PR-latch bits are used to select 1 of 16 possible column addresses as the next column address.
JLL	Jump/test leftmost PR-latch bits. AC_0-AC_2 are used to select 1 of 8 row addresses in the current row group, specified by MA_7 and MA_8, as the next row address. PR_2 and PR_3 are used to select 1 of 4 column addresses in col_4 through col_7 as the next column address.
JRL	Jump/test rightmost PR-latch bits. AC_0 and AC_1 are used to select 1 of 4 high-order row addresses in the current row group, specified by MA_7 and MA_8, as the next row address. PR_0 and PR_1 are used to select 1 of 4 possible column addresses in col_{12} through col_{16} as the next column address.
JPX	Jump/test PX-bus and load PR-latch. AC_0 and AC_1 are used to select 1 of 4 row addresses in the current row group, specified by MA_6-MA_8, as the next row address. PX_4-PX_7 are used to select 1 of 16 possible column addresses as the next column address. SX_0-SX_3 data is locked in the PR-latch at the rising edge of the clock.

©IC MASTER 1978

PX-Bus and PR-Latch Conditional Address Control (Jump/Test) Functions

The PX-bus jump/test function uses the data on the primary instruction bus (PX_4-PX_7), the current microprogram address, and several selection bits from the address control function to generate the next microprogram address. The PR-latch jump/test functions use the data held in the PR-latch, the current microprogram address, and several selection bits from the address control function to generate the next microprogram address.

Flag Control Functions

The flag control functions of the MCU are selected by the 4 input lines designated FC_0-FC_3. Function code formats are given in "Flag Control Function summary."

The following is a detailed description of each of the 8 flag control functions.

Flag Input Control Functions

The flag input control functions select which flag or flags will be set to the current value of the flag input ($\overline{FI}$) line.

Data on $\overline{FI}$ is stored in the F-latch when the clock is low. The content of the F-latch is loaded into the C and/or Z flag on the rising edge of the clock.

Flag Output Control Functions

The flag output control functions select the value to which the flag output ($\overline{FO}$) line will be forced.

FLAG CONTROL FUNCTION TABLE

MNEMONIC	FUNCTION DESCRIPTION
SCZ	Set C-flag and Z-flag to FI. The C-flag and the Z-flag are both set to the value of FI.
STZ	Set Z-flag to FI. The Z-flag is set to the value of FI. The C-flag is unaffected.
STC	Set C-flag to FI. The C-flag is set to the value of FI. The Z-flag is unaffected.
HCZ	Hold C-flag and Z-flag. The values in the C-flag and Z-flag are unaffected.

FLAG OUTPUT CONTROL FUNCTION TABLE

MNEMONIC	FUNCTION DESCRIPTION
FF0	Force FO to 0. FO is forced to the value of logical 0.
FFC	Force FO to C. FO is forced to the value of the C-flag.
FFZ	Force FO to Z. FO is forced to the value of the Z-flag.
FF1	Force FO to 1. FO is forced to the value of logical 1.

FLAG CONTROL FUNCTION SUMMARY

TYPE	MNEMONIC	DESCRIPTION	FC_1	0
Flag Input	SCZ	Set C-flag and Z-flag to f	0	0
	STZ	Set Z-flag to f	0	1
	STC	Set C-flag to f	1	0
	HCZ	Hold C-flag and Z-flag	1	1

TYPE	MNEMONIC	DESCRIPTION	FC_3	2
Flag Output	FF0	Force FO to 0	0	0
	FFC	Force FO to C-flag	1	0
	FFZ	Force FO to Z-flag	0	1
	FF1	Force FO to 1	1	1

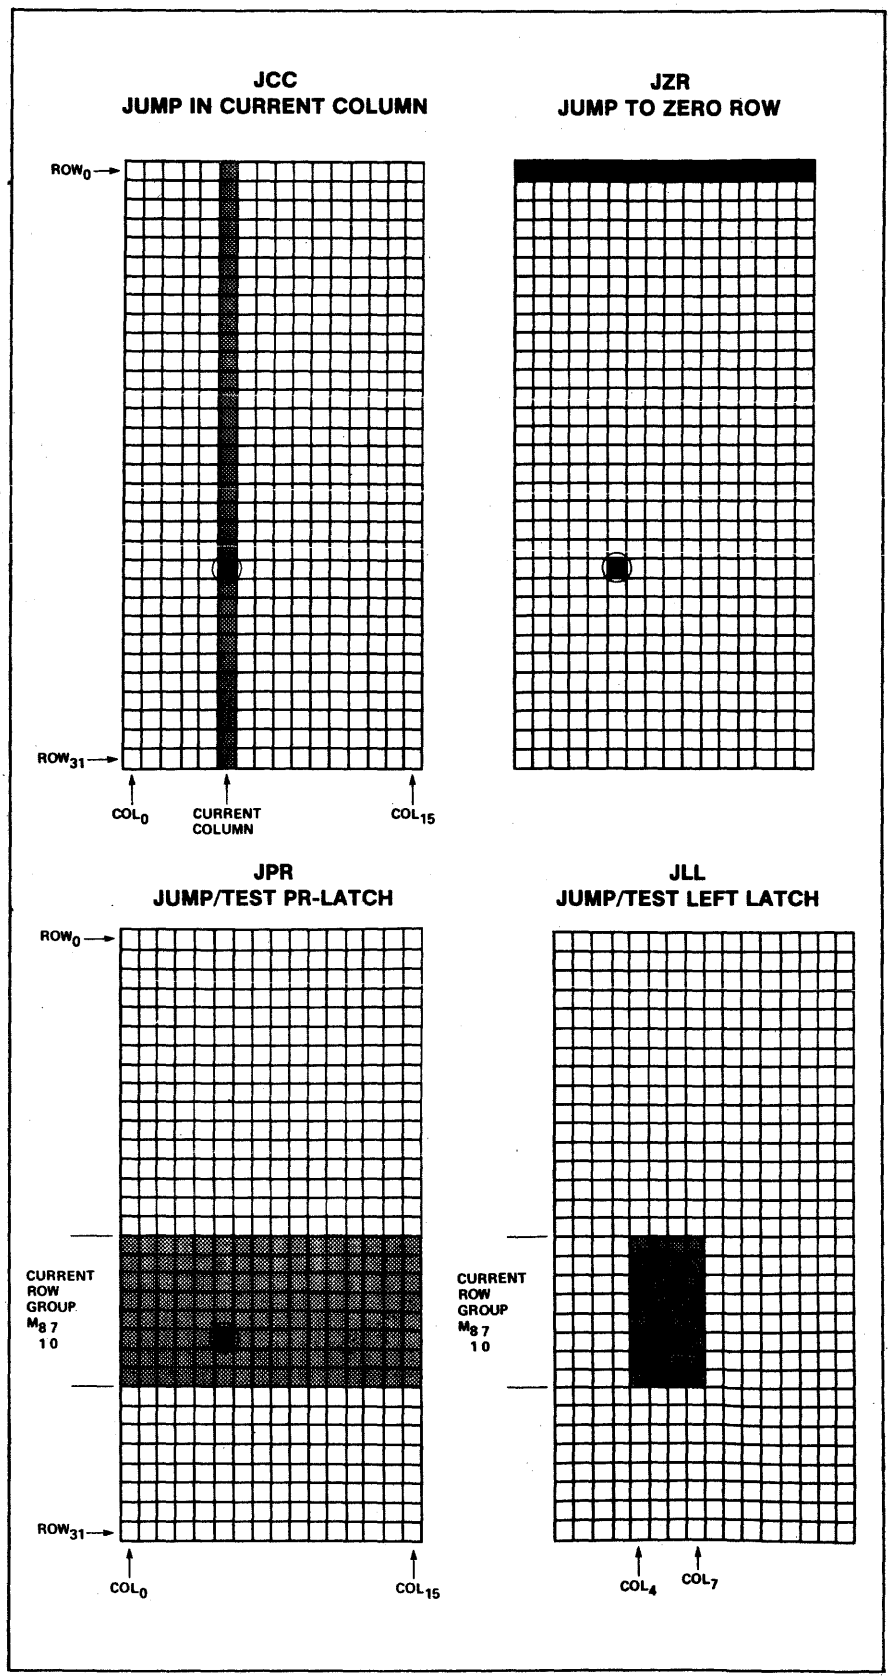
Pn = Data in PR-latch bit n
xn = Data on PX-bus line n (active low)
f,c,z = Contents of F-latch, C-flag, or Z-flag, respectively

©IC MASTER 1978

STROBE FUNCTIONS

The load function of the MCU is controlled by the input line designated LD. If the LD line is active high at the rising edge of the clock, the data on the primary and secondary instruction buses, PX_4-PX_7 and SX_0-SX_3, is loaded into the microprogram address register. PX_4-PX_7 are loaded into MA_0-MA_7 and SX_0-SX_3 are loaded into MA_4-MA_7. The high-order bit of the microprogram address register MA_8 is set to a logical 0. The bits from the primary instruction bus select 1 of 16 possible column addresses. Likewise, the bits from the secondary instruction bus select 1 of the first 16 row addresses.



The MCU generates an interrupt strobe enable on the output line designated ISE. The line is placed in the active high state whenever a JZR to col_{15} is selected as the address control function. Generally, the start of a macroinstruction fetch sequence is situated at row_0 and col_{15} so the interrupt control may be enabled at the beginning of the fetch/execute cycle. The interrupt control responds to the interrupt by pulling the enable row address (ERA) input line low to override the selected next row address from the MCU. Then by gating an alternative next row address on to the row address lines of the microprogram memory, the microprogram may be forced to enter an interrupt handling routine. The alternative row address placed on the microprogram memory address lines does not alter the contents of the microprogram address register. Therefore, subsequent jump functions will utilize the row address in the register, and not the alternative row address, to determine the next microprogram address.

Note, the load function always overrides the address control function on AC_0-AC_6. It does not, however, override the latch enable or load sub-functions of the JCE or JPX instruction, respectively. In addition, it does not inhibit the interrupt strobe enable or any of the flag control functions.

JUMP SET DIAGRAMS

The following 10 diagrams illustrate the jump set for each of the 11 jump and jump/test functions of the MCU. Location 341 indicated by the circled square, represents 1 current row (row_{21}) and current column (col_5) address. The dark boxes indicate the microprogram locations that may be selected by the particular function as the next address.

DESCRIPTION

The N3002 Central Processing Element (CPE) is one part of a bipolar microcomputer set. The N3002 is organized as a 2-bit slice and performs the logical and arithmetic functions required by microinstructions. A system with any number of bits in a data word can be implemented by using multiple N3002s, the N3001 microcomputer control unit, the N74S182 carry look-ahead unit and ROM or PROM memory.

FEATURES

- **45ns cycle time (typ)**
- **Easy expansion to multiple of 2 bits**
- **11 general purpose registers**
- **Full function accumulator**
- **Useful functions include:**
  - **2's complement arithmetic**
  - **Logical AND, OR, NOT, exclusive-NOR**
  - **Increment, decrement**
  - **Shift left/shift right**
  - **Bit testing and zero detection**
  - **Carry look-ahead generation**
  - **Masking via K-bus**
  - **Conditioned clocking allowing non-destructive testing of data in accumulator and scratchpad**
- **3 input buses**
- **2 output buses**
- **Control bus**

SYSTEM DESCRIPTION

Microfunction Decoder and K-Bus

Basic microfunctions are controlled by a 7-bit bus (F_0-F_6) which is organized into 2 groups. The higher 3 bits (F_4-F_6) are designated as F-Group and the lower 4 bits (F_0-F_3) are designated as the R-Group. The F-Group specifies the type of operation to be performed and the R-Group specifies the registers involved.

The F-Bus instructs the microfunction decoder to:
- Select ALU functions to be performed
- Generate scratchpad register address
- Control A and B multiplexer

The resulting microfunction action can be:
- Data transfer
- Shift operations
- Increment and decrement
- Initialize stack
- Test for zero conditions
- 2's complement addition and subtraction
- Bit masking
- Maintain program counter

A and B Multiplexers

A and B multiplexers select the proper 2 operands to the ALU.

A multiplexer selects inputs from one of the following:
- M-bus (data from main memory)
- Scratchpad registers
- Accumulator

B multiplexer selects inputs from one of the following:
- I-bus (data from external I/O devices)
- Accumulator
- K-bus (literal or masking information from micro-program memory)

Scratchpad Registers

- Contains 11 registers (R_0-R_9, T)
- Scratchpad register outputs are multiplexed to the ALU via the A multiplexer
- Used to store intermediate results from arithmetic/logic operations
- Can be used as program counter

Arithmetic/Logic Unit (ALU)

The ALU performs the arithmetic and logic operations of the CPE.

Arithmetic operations are:
- 2's complement addition
- Incrementing
- Decrementing
- Shift left
- Shift right

Logical operations are:
- Transfer
- AND
- Inclusive-OR
- Exclusive-NOR
- Logic complement

ALU operation results are then stored in the accumulator and/or scratchpad registers. For easy expansion to larger arrays, carry look-ahead outputs (X and Y) and cascading shift inputs (LI, RO) are provided.

signetics

©IC MASTER 1978

Accumulator

- Stores results from ALU operations
- The output of accumulator is multiplexed into ALU via the A and B multiplexer as one of the operands

Input Buses

M-bus: Data bus from main memory
- Accepts 2 bits of data from main memory into CPE
- Is multiplexed into the ALU via the A multiplexer

I-bus: Data bus from input/output devices
- Accepts 2 bits of data from external input/output devices into CPE
- Is multiplexed into the ALU via the B multiplexer

K-bus: A special feature of the N3002 CPE
- During arithmetic operations, the K-bus can be used to **mask** portions of the field being operated on
- Select or remove accumulator from operation by placing K-bus in all "1" or all "0" state respectively
- During non-arithmetic operation, the carry circuit can be used in conjunction with the K-bus for word-wise-OR operation for bit testing
- Supply literal or constant data to CPE

Output Buses

A-bus and Memory Address Register
- Main memory address is stored in the memory address register (MAR)
- Main memory is addressed via the A-bus
- MAR and A-bus may also be used to generate device address when executing I/OO instruc-instructions
- A-bus has Tri-State outputs

D-bus: Data bus from CPE to main memory or to I/O devices
- Sends buffered accumulator outputs to main memory or the external I/O devices
- D-bus has Tri-State outputs

FUNCTION DESCRIPTION

F GROUP	R GROUP	K BUS	NAME	EQUATION	DESCRIPTION
0	I	XX	—	$R_n + (AC \wedge K) + CI \rightarrow R_n, AC$	**Logically AND AC with the K-bus.** Add the result to R_n and carry input (CI). Deposit the sum in AC and R_n.
		OO	ILR	$R_n + CI \rightarrow R_n, AC$	Conditionally increment R_n and load the result in AC. Used to load AC from R_n or to increment R_n and load a copy of the result in AC.
		11	ALR	$AC + R_n + CI \rightarrow R_n, AC$	Add AC and CI to R_n and load the result in AC. Used to add AC to a register. If R_n is AC, then AC is shifted left one bit position.
0	II	XX	—	$M + (AC \wedge K) + CI \rightarrow AT$	**Logically AND AC with the K-bus.** Add the result to CI and the M-bus. Deposit the sum in AC or T.
		OO	ACM	$M + CI \rightarrow AT$	Add CI to M-bus. Load the result in AC or T, as specified. Used to load memory data in the specified register, or to load incremented memory data in the specified register.
		11	AMA	$M + AC + CI \rightarrow AT$	Add the M-bus to AC and CI, and load the result in AC or T, as specified. Used to add memory data or incremented memory data to AC and store the sum in the specified register.
0	III	XX	—	$AT_L \wedge (\overline{I_L \wedge K_L}) \rightarrow RO$ $LI \vee [(I_H \wedge K_H) \wedge AT_H] \rightarrow AT_H$ $[AT_L \wedge (I_L \wedge K_L)]$ $[AT_H \vee (I_H \wedge K_H)] \rightarrow AT_L$	None
		OO	SRA	$AT_L \rightarrow RO$ $AT_H \rightarrow AT_L$ $L_I \rightarrow AT_H$	Shift AC or T, as specified, right one bit position. Place the previous low order bit value on RO and fill the high order bit from the data on LI. Used to shift or rotate AC or T right one bit.
1	I	XX	—	$K \vee R_n \rightarrow MAR$ $R_n + K + CI \rightarrow R_n$	**Logically OR R_n with the K-bus.** Deposit the result in MAR. Add the K-bus to Rn and CI. Deposit the result in R_n.
		OO	LMI	$Rn \rightarrow MAR,\ Rn + CI \rightarrow Rn$	Load MAR from R_n. Conditionally increment R_n. Used to maintain a macro-instruction program counter.
		11	DSM	$11 \rightarrow MAR,\ Rn - 1 + CI \rightarrow Rn$	Set MAR to all ones. Conditionally decrement R_n by one. Used to force MAR to its highest address and to decrement Rn.
1	II	XX	—	$KVM \rightarrow MAR$ $M + K + CI \rightarrow AT$	**Logically OR the M-bus with the K-Bus.** Deposit the result in MAR. Add the K-bus to the M-bus and CI. Deposit the sum in AC or T.
		OO	LMM	$M \rightarrow MAR,\ M + CI \rightarrow AT$	Load MAR from the M-bus. Add CI to the M-bus. Deposit the result in AC or T. Used to load the address register with memory data for macro-instructions using indirect addressing.
		11	LDM	$11 \rightarrow MAR$ $M - 1 + CI \rightarrow AT$	Set MAR to all ones. Subtract one from the M-bus. Add CI to the difference and deposit the result in AC or T, as specified. Used to load decremented memory data in AC or T.

FUNCTION DESCRIPTION (Cont'd)

F GROUP	R GROUP	K BUS	NAME	EQUATION	DESCRIPTION
1	III	XX	—	$(\overline{AT} \vee K) + (AT \wedge K) + CI \rightarrow AT$	**Logically OR the K-bus with the complement of AC or T, as specified.** Add the result to the logical AND of specified register with the K-bus. Add the sum to CI. Deposit the result in the specified register.
		OO	CIA	$\overline{AT} + CI \rightarrow AT$	Add CI to the complement of AC or T, as specified. Deposit the result in the specified register. Used to form the 1's or 2's complement of AC or T.
		11	DCA	$\overline{AT} - 1 + CI \rightarrow AT$	Subtract one from AC or T, as specified. Add CI to the difference and deposit the sum in the specified register. Used to decrement AC or T.
2	I	XX	—	$(AC \wedge K) - 1 + CI \rightarrow R_n$	**Logically AND the K-bus with AC.** Subtract one from the result and add the difference to CI. Deposit the sum in R_n.
		OO	CSR	$CI - 1 \rightarrow R_n$ (See Note 1)	Subtract one from CI and deposit the difference in Rn. Used to conditionally clear or set R_n to all 0's or 1's, respectively.
		11	SDR	$AC - 1 + CI \rightarrow R_n$ (See Note 1)	Subtract one from AC and add the difference to CI. Deposit the sum in R_n. Used to store AC in R_n or to store the decremented value of AC in R_n.
2	II	XX	—	$(AC \wedge K) - 1 + CI \rightarrow AT$ (See Note 1)	**Logically AND the K-bus with AC.** Subtract one from the result and add the difference to CI. Deposit the sum in AC or T, as specified.
		OO	CSA	$CI - 1 \rightarrow AT$ (See Note 1)	Subtract one from CI and deposit the difference in AC or T. Used to conditionally clear or set AC or T.
		11	SDA	$AC - 1 + CI \rightarrow AT$ (See Note 1)	Subtract one from AC and add the difference to CI. Deposit the sum in AC or T. Used to store AC in T, or decrement AC, or store the decremented value of AC in T.
2	III	XX	—	$(I \wedge K) - 1 + CI \rightarrow AT$ (See Note 1)	**Logically AND the data of the K-bus with the data on the I-bus.** Subtract one from the result and add the difference to CI. Deposit the sum in AC or T, as specified.
		OO	CSA	$CI - 1 \rightarrow AT$	Subtract one from CI and deposit the difference in AC or T. Used to conditionally clear or set AC or T.
		11	LDI	$I - 1 + CI \rightarrow AT$	Subtract one from the data on the I-bus and add the difference to CI. Deposit the sum in AC or T, as specified. Used to load input bus data or decremented input bus data in the specified register.
3	I	XX	—	$R_n + (AC \wedge K) + CI \rightarrow R_n$	**Logically AND AC with the K-bus.** Add R_n and CI to the result. Deposit the sum in R_n.
		OO	INR	$R_n + CI \rightarrow R_n$	Add CI to R_n and deposit the sum in R_n. Used to increment R_n.
		11	ADR	$AC + R_n + CI \rightarrow R_n$	Add AC to R_n. Add the result to CI and deposit the sum in R_n. Used to add the accumulator to a register or to add the incremented value of the accumulator to a register.
3	II	XX	—	$M + (AC \wedge K) + CI \rightarrow AT$	**Logically AND AC with the K-bus.** Add the result to CI and the M-bus. Deposit the sum in AC or T.
		OO	ACM	$M + CI \rightarrow AT$	Add CI to M-bus. Load the result in AC or T, as specified. Used to load memory data in the specified register, or to load incremented memory data in the specified register.
		11	AMA	$M + AC + CI \rightarrow AT$	Add the M-bus to AC and CI, and load the result in AC or T, as specified. Used to add memory data or incremented memory data to AC and store the sum in the specified register.

NOTE

1. 2's complement arithmetic adds 111 . . . 11 to perform subtraction of 000 . . . 01.

©IC MASTER 1978

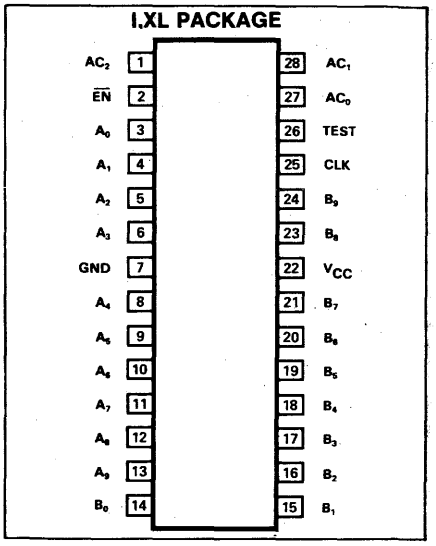
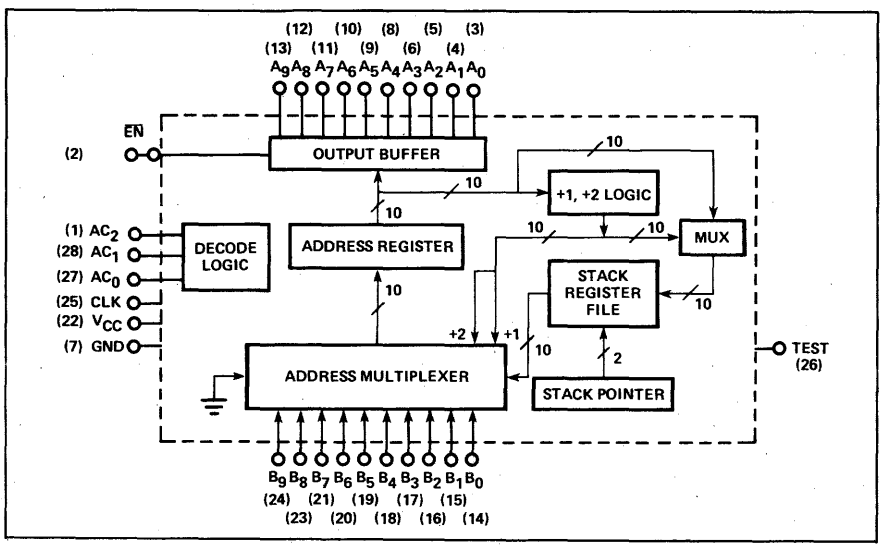
PRELIMINARY SPECIFICATION 8X02-I,XL



DESCRIPTION

The Signetics 8X02 is a low power Schottky LSI device intended for use in high performance microprogrammed systems to control the fetch sequence of microinstructions. When combined with standard ROM or PROM, the 8X02 forms a powerful microprogrammed control section for computers, controllers, or sequential logic.



FEATURES

- **Low power Schottky process**
- **1024 microinstruction addressability**
- **N-way branch**
- **4-level stack register file (LIFO type)**
- **Automatic push/pop stack operation**
- **"Test and skip" operation on test input line**
- **3-bit command code**
- **Tri-state buffered outputs**
- **Auto-reset to address 0 during power-up**
- **Conditional branching, pop stack, and push stack**

PIN CONFIGURATION

BLOCK DIAGRAM

PIN DESIGNATION

PIN	SYMBOL	NAME AND FUNCTION	TYPE
5-6 8-13	A_0-A_9	Microprogram Address outputs	Three-state Active high
1,28,27	AC_0-AC_2	Next Address Control Function inputs All addressing control functions are selected by these command lines.	Active high
14-21 23-24	B_0-B_9	Branch Address inputs Determines the next address of an N-way branch when used with the BRANCH TO SUBROUTINE (BSR) or BRANCH ON TEST (BRT) command.	Active high
2	$\overline{EN}$	Enable input When in the low state, the Microprogram Address outputs are enabled.	Active low
25	CLK	Clock Input—High to Low transition for stack operations, Low to High transition for address modification.	⊓
26	TEST	Test input Used in conjunction with four NEXT ADDRESS CONTROL FUNCTION commands to effect conditional skips, branches, and stack operations.	Active high
7	GND	Ground	
22	V_{CC}	+5 Volt supply

FUNCTIONAL DESCRIPTION

The Signetics 8X02 Control Store Sequencer is an LSI device using low power Schottky technology and is intended for use in high performance microprogrammed applications. When used alone, the 8X02 is capable of addressing up to 1K words of microprogram. This may be expanded to any microprogram size by conventional paging techniques.

The Address Register consists of 10 D-type, edge-triggered flip-flops with a common clock. A new address is entered into the Address Register on the low-to-high transition of the clock. The next address to be entered into the Address Register is supplied via the Address Multiplexer.

The Address Multiplexer is a 5-input device that is used to select either the branch input, +1 adder, +2 adder, stack register file, or ground (all zeros) as the source of the next microinstruction address. The proper multiplexer channel is automatically selected via the Decode Logic according to the Address Control Function Input and Test Input line.

The +1, +2 logic is used to increment the present contents of the Address Register by 1 or 2, depending on the function input command. Thus, the next address to the Control Store ROM/PROM may be either the current address plus 1 (N+1) or the current address plus 2 (N+2). If the same Microprogram Address is to be used on successive occasions, the clock to the 8X02 must simply be disabled; therefore, no new address is loaded into the Address Register.

The Stack File Register is used to provide a return address linkage whenever a subroutine or loop is executed. The 4X10 stack operates in a last-in, first-out (LIFO) mode, with the stack pointer always pointing to the next address to be read. Operation of the stack pointer is automatically controlled by the Address Control Function Inputs. Since the stack is 4 words deep, up to 4 loops and/or subroutines may be nested.

The branch input is a 10-bit field of direct inputs to the multiplexer which can be selected as the next control store address. Using the appropriate branch command, an N-way branch is possible where N is the address of any microinstruction within the 1024 word microcode page. Likewise, the RESET command is a special case of an N-way branch in which the multiplexer selects an all zeros input, forcing the next microinstruction address to be zero.

The Test Input line is used in conjunction with the conditional execution of 4 Address Control Function commands. When the Test Input is false (low), the sequencer simply increments to the next address (N+1). When it is true (high), the sequencer executes a branch as defined by the input command, thereby transferring control to another portion of the microprogram.

All Address Output lines of the 8X02 are three-state buffered outputs with a common enable line ($\overline{EN}$). When the Enable line is high, all outputs are placed in a high-impedance state, and external access to the control store ROM/PROM is possible. This allows a preprogrammed set of microinstructions to be executed from external or built-in test equipment (BITE), vectored interrupts, and Writable Control Store if implemented.

NEXT ADDRESS CONTROL FUNCTION TABLE

MNEMONIC	DESCRIPTION	FUNCTION AC_2 1 0	TEST	NEXT ADDRESS	STACK	STACK POINTER
TSK	Test and skip	0 0 0	False True	Current + 1 Current + 2	N.C. N.C.	N.C. N.C.

FUNCTIONAL DESCRIPTION

The following is a description of each of the eight Next Address Control Functions (AC_2-AC_0)

MNEMONIC	FUNCTION DESCRIPTION
TSK	AC_{2-0} = 000: TEST AND SKIP Perform test on Test Input Line. If test is False (Low): Next Address = Current Address + 1 Stack Pointer unchanged If test is True (High): Next Address = Current Address + 2 (i.e. Skip next microinstruction) Stack Pointer unchanged
INC	AC_{2-0} = 001: INCREMENT Next Address = Current Address + 1 Stack Pointer unchanged
BLT	AC_{2-0} = -010: BRANCH TO LOOP IF TEST CONDITION TRUE. Perform test on Test Input Line. If test is False (Low): Next Address = Current Address + 1 Stack Pointer decremented by 1 If test is True (High): Next Address = Address from Stack Register File (POP) Stack Pointer decremented by 1
POP	AC_{2-0} = 011: POP STACK Next Address = Address from Stack Register File (POP) Stack Pointer decremented by 1
BSR	AC_{2-0} = 100: BRANCH TO SUBROUTINE IF TEST CONDITION TRUE. Perform test on Test Input Line. If test is False (Low): Next Address = Current Address + 1 Stack Pointer unchanged If test is True (High): Next Address = Branch Address Input (B_{0-9}) Stack Pointer incremented by 1 PUSH (write) Current Address + 1 → Stack Register File
PLP	AC_{2-0} = 101: PUSH FOR LOOPING Next Address = Current Address + 1 Stack Pointer incremented by 1 PUSH (write) Current Address → Stack Register File
BRT	AC_{2-0} = 110: BRANCH ON TEST CONDITION TRUE Perform test on Test Input Line. If test is False (Low): Next Address = Current Address + 1 Stack Pointer unchanged If test is True (High): Next Address = Branch Address Input (B_{0-9}) Stack Pointer unchanged
RST	AC_{2-0} = 111: RESET TO ZERO Next Address = 0 Stack Pointer unchanged

DESCRIPTION

The Signetics 8X300 Microcontroller is a monolithic, high-speed microprocessor implemented with bipolar Schottky technology. As the central processing unit, CPU, it allows 16-bit instructions to be fetched, decoded and executed in 250ns. A 250ns instruction cycle requires maximum memory access of 65ns, and maximum I/O device access of 35ns.

Microcontroller instructions operate on 8-bit, parallel data. Logic is distributed along the data path within the Microcontroller. Input data can be rotated and masked before being subject to an arithmetic or logical operation; and output data can be shifted and merged with the input data, before being output to external logic. This allows 1- to 8-bit I/O and data memory fields to be accessed and processed in a single instruction cycle.

PROGRAM STORAGE INTERFACE

Program Storage is typically connected to the A0-A12 (A12 is least significant bit) and I0-I15 signal lines. An address output on A0-A12 identifies one 16-bit instruction word in program storage. The instruction word is subsequently input on I0-I15 and defines the Microcontroller operations which are to follow.

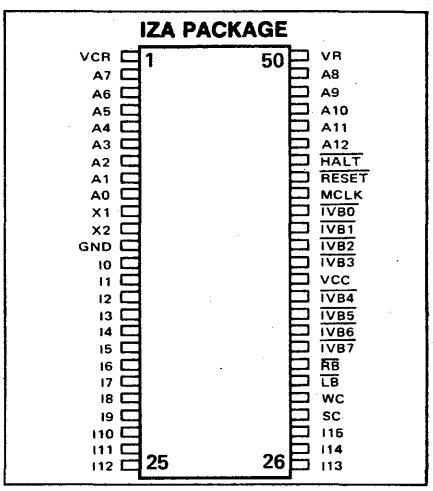
The Signetics 82S115 PROM, or any TTL compatible memory, may be used for program storage.

I/O DEVICES INTERFACE

An 8-bit I/O bus, called the Interface Vector (IV) data bus, is used by the Microcontroller to communicate with 2 fields of I/O devices. The complementary $\overline{LB}$ and $\overline{RB}$ signals identify which field of the I/O devices is selected.

Both I/O data and I/O address information can be output on the IV bus. The SC and WC signals are typically used to distinguish between I/O data and I/O address information as follows:

SC	WC	
1	0	I/O address is being output on IV bus
0	1	I/O data is being output on IV bus
0	0	I/O data is expected on the IV, bus, as input to the Microcontroller
1	1	Not generated by the Microcontroller



The Signetics 82SXXX series RAM, and the 8T32/33 may be attached to the IV bus.

FEATURES

- **185ns instruction decode and execute delay (with Signetics 8T32/33 I/O port)**
- **Eight 8-bit working registers**
- **Single instruction access to 1-bit, 2-bit, 3-bit or 8-bit field on I/O bus**
- **Separate instruction address, instruction, and I/O data buses**
- **On-chip oscillator**
- **Bipolar Schottky technology**
- **TTL inputs and outputs**
- **Tri-state output on I/O data bus**
- **+5 volt operation from 0° to 70°C**

PIN CONFIGURATION

IZA PACKAGE

PIN DESIGNATION

PIN	SYMBOL	NAME AND FUNCTION	TYPE
2-9, 45-49	A0-A12:	Instruction address lines. A high level equals "1." These outputs directly address up to 8192 words of program storage. A12 is least significant bit.	Active high
13-28	I0-I15:	Instruction lines. A high level equals "1." Receives instructions from Program Storage. I_{15} is least significant bit.	Active high
33-36, 38-41	$\overline{IVB0}$-$\overline{IVB7}$	Interface Vector (IV) Bus. A low level equals "1." Bidirectional tri-state lines to communicate with I/O devices. $\overline{IVB7}$ is least significant bit.	Three-state Active low
42	$\overline{MCLK}$:	Master Clock. Output to clock I/O devices, and/or provide synchronization for external logic	
30	WC:	Write Command. High level output indicates data is being output on the IV Bus.	Active high
29	SC:	Select Command. High level output indicates that an address is being output on the IV Bus.	Active high
31	$\overline{LB}$:	Left Bank. Low level output to enable one of two sets of I/O devices ($\overline{LB}$ is the complement of RB).	Active low
32	$\overline{RB}$:	Right Bank. Low level output to enable one of two sets of I/O devices ($\overline{RB}$ is the complement of $\overline{LB}$).	Active low
44	$\overline{HALT}$:	Low level is input to stop the Microcontroller.	Active low
43	$\overline{RESET}$:	Low level is input to initialize the Microcontroller.	Active low
10-11	X1, X2:	Inputs for an external frequency determining crystal. May also be interfaced to logic or test equipment.	
50	VR	Reference voltage to pass transistor.	
1	VCR	Regulated output voltage from pass transistor.	
37	V_{CC}:	5V power connection.	
12	GND:	Ground.

MICROCONTROLLER ARCHITECTURE

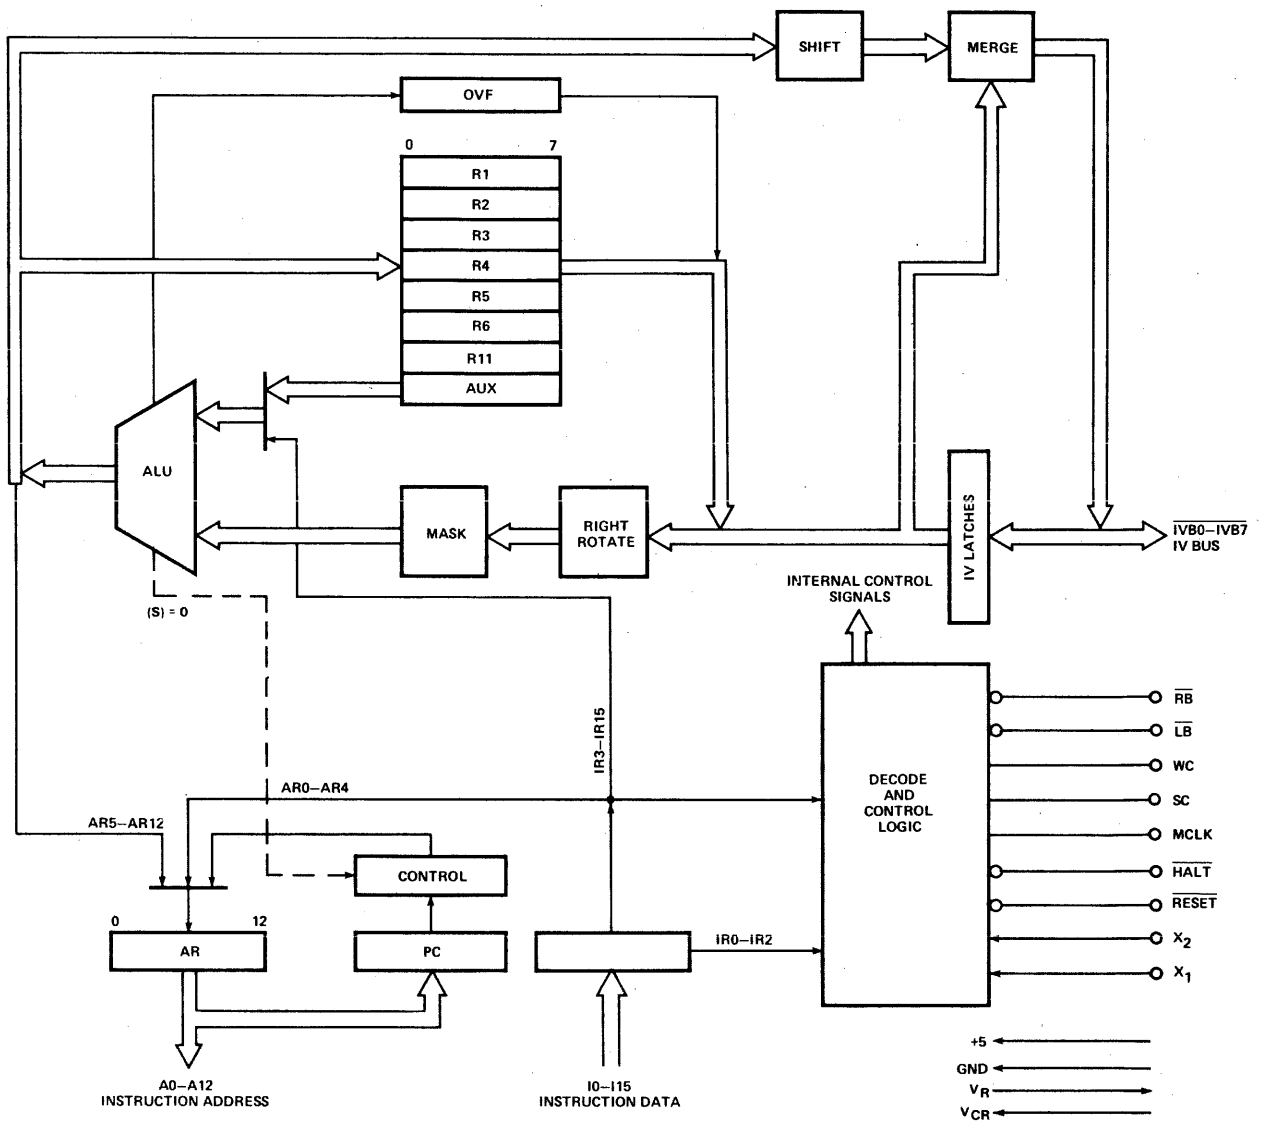

Figure 1

R1 — General working register
R2 — General working register
R3 — General working register
R4 — General working register
R5 — General working register
R6 — General working register
R11 — General working register
AUX — General working register. Contains second term for arithmetic or logical operations.

OVF — The least-significant bit of this register is used to reflect overflow status resulting from the most recent ADD operation (see Instruction Set Summary).

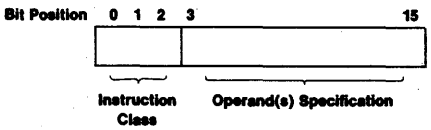
Instruction Register (IR)
— Holds the 16-bit instruction word currently being executed.

Program Counter (PC)
— Normally contains the address of the current instruction and is incremented to obtain the next instruction address.

Address Register (AR)
— A 13-bit register containing the address of the current instruction.

Table 1 INTERNAL REGISTERS

©IC MASTER 1978



INSTRUCTION CYCLE

Each Microcontroller operation is executed in 1 instruction cycle, which may be as short as 250ns. The Microcontroller generates MCLK to synchronize external logic to the instruction cycle. Instruction cycles are subdivided into quarter cycles. MCLK is an output during the last quarter cycle.

During the third quarter cycle of an instruction, an address is output on A0-A12, identifying the location in program storage of the next instruction word. This instruction word defines the next instruction, which must be input on I0-I15 during the first quarter cycle of the next instruction cycle (see Table 2).

Instruction Set Summary

The 16-bit instruction word input on I0-I15 is decoded by the instruction decode logic to implement events that are to occur during the remainder of the instruction cycle. Generally the 16-bit instruction word is decoded as follows:

A detailed usage of the 13 "operand(s) specification" bits is given in following sections.

Three operation code bits allow for 8 instruction classes. The 8 instruction classes are summarized in Table 3. Each entry is referred to as an "instruction class" because the unique architecture of the Interpreter allows a number of powerful variations to be specified by the 13 operand(s) specification bits. A complete description of instruction formats and some instruction examples are provided in the Microprocessor Applications manual.

Data Processing

The Microcontroller architecture includes eight 8-bit working registers, an arithmetic logic unit (ALU), an overflow register, and the 8-bit IV Bus. Internal 8-bit data paths connect the registers and IV Bus to the ALU inputs, and the ALU output to the registers and IV Bus. Data processing logic is distributed along these internal 8-bit data paths. Rotate and mask logic precedes the ALU on the data entry path. Shift and merge logic follows the ALU on the data output path. All 4 sets of logic can operate on 8 data bits in a single instruction cycle (See Figure 1).

When less than 8 bits of data are specified for output to the IV bus by the ALU, the data field (shifted if necessary) is inserted into the prior contents of the IV bus latches. The IV bus latches contain data input at the start of an instruction. This data in the IV bus latches will be specified in the instruction as a) IV bus source data or b) data from an automatic read when the IV bus is specified as a destination. Therefore, IV bus bit positions outside an inserted bit field are unmodified.

Data Addressing

Sources and destinations of data are specified using a 5-bit octal number. The source and/or destination of data to be operated upon is specified in a single instruction word.

Referring to Figure 1, the Auxiliary register (address 00) is the implied source of the second argument for ADD, AND or XOR operations.

IVL and IVR are write-only registers used only as a destination. They have addresses and are treated as registers, but in reality they do not exist. When IVL is specified as a destination or the D field = $20\text{-}27_8$, then LB = 'low', RB = 'high' are generated; when IVR is specified as a destination or the D field = $30\text{-}37_8$, then RB = low, LB = 'high' are generated.

When IVL or IVR is specified as the destination in an instruction, SC is also activated and data is placed on the IV bus. If IVL or IVR is specified as a source of data, the source data is all zeroes.

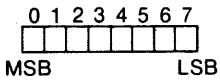
Table 2 INSTRUCTION CYCLE

INSTRUCTION SEQUENCE CONTROL

The Address Register and Program Counter are used to generate addresses for accessing an instruction. The Address Register is used to form the instruction address, and in all but 3 instructions (XEC, NZT, and JMP) the address is copied into the Program Counter. The instruction address is formed in 1 of 3 ways:



1. For all instructions but the JMP, XEC, and a satisfied NZT, the Program Counter is incremented by 1 and placed in the Address Register.
2. For the JMP instruction, the full 13-bit address field from the JMP instruction is placed into the Address Register and copied into the Program Counter.
3. For the XEC and NZT instructions, the high order 5- or 8-bits of the Program Counter are combined with 8- or 5-lower-order bits of ALU output (XEC or NZT) and placed in the Address Register. For the NZT instruction, it is also copied into the Program Counter.

©IC MASTER 1978

INSTRUCTION SET

The 8X300 Microcontroller has a repertoire of 8 instruction classes which allow the user to test input status lines, set or reset output control lines, and perform high speed input/output data transfers. All instructions are 16 bits in length and each is fetched, decoded and executed in 250ns.

Data is respresented as an 8-bit byte; bit positions are numbered from left to right, with the least significant bit in position 7.

Within the 8X300, all operations are performed on 8-bit bytes. Arithmetic operations use 8-bit, unsigned 2's complement arithmetic.

INSTRUCTION FORMATS

The general 8X300 instruction format is:

0 1 2	3 4 5 6 7 8 9 10 11 12 13 14 15
Op Code	Operand(s)

All instructions are specified by a 3-bit Operation (Op Code) field. The operand may consist of the following fields: Source (S) field, Destination (D) field, Rotate/Length (R/L) field, Immediate (I) field, or (Program Storage) Address (A) field.

The instructions are divided into 5 format types, based on the Op Code and the Operand(s), as shown in Figure 3.

OPERATION	FORMAT	RESULT	NOTES
MOVE	I,II	Content of data field specified by {S, R/L} replaces data in field specified by {D, R/L.}	If S and D both are registers, then R/L specifies a right rotate of the register specified by S.
ADD	I,II	Sum of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L}.	
AND	I,II	Logical AND of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L.}	
XOR	I,II	Logical exclusive OR of AUX and data specified by {S, R/L} replaces data in field specified by {D, R/L.}	
XMIT	III,IV	The literal value I replaces the data in the field specified by {S,L.}	If S is an I/O address then I is limited to range 00-37. Otherwise I is limited to range 000-377.
NZT	III,IV	If the data in the field specified by {S, L} equals zero, perform the next instruction in sequence. If the data specified by {S,L} is not equal to zero, execute the instruction at address determined by using the literal I as an offset to the Program Counter.	If S is an I/O address then I is limited to range 00-37. Otherwise I is limited to range 000-377.
XEC	III,IV	Perform the instruction at address determined by applying the sum of the literal I and the data specified by {S, L} as an offset to the Program Counter. If that instruction does not transfer control, the program sequence will continue from the XEC instruction location.	The offset operation is performed by reducing the value of PC to the nearest multiple of 32 (if I = 00-37) or 256 (if I = 000-377) and adding the offset.
JMP	V	The address value A replaces contents of the Program Counter.	A limited to the range $0\text{-}17777_8$.

INSTRUCTION FIELDS

Op Code Field (3-Bit Field)

The Op Code field is used to specify 1 or 8 8X300 instructions as shown in Table 4.

OP CODE OCTAL VALUE	INSTRUCTION	
0	MOVE	S,R/L,D
1	ADD	S,R/L,D
2	AND	S,R/L,D
3	XOR	S,R/L,D
4	XEC	I,R/L,S or I,S
5	NZT	I,R/L,S or I,S
6	XMIT	I,R/L,D or I,D
7	JMP	A

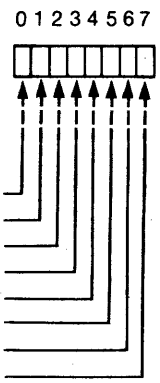
Table 4 OP CODE FIELD OCTAL ASSIGNMENTS

S,D Fields (5-Bit Fields)

The S and D fields specify the source and destination of data for the operation defined by the Op Code field. The Auxiliary Register is an implied second source for the instructions ADD, AND and XOR, each of which require two source fields. That is, instructions of the form,

ADD X, Y

imply a third operand, say Z, located in the Auxiliary Register so that the operation which takes place is actually X + Z, with the result stored in Y.

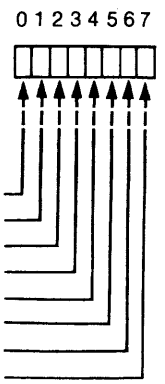


The S and/or D fields may specify a register, or a 1 to 8-bit I/O field. S and D field value assignments in octal are shown in Table 5.

0_8-17_8 is used to specify 1 of 7 working registers (R1-R6, R11), the Auxiliary Register, the Overflow Register, or IVL and IVR write-only registers.

OCTAL VALUE		OCTAL VALUE	
00	AUX-Auxiliary Register	10	OVF-Overflow register-Used only as a source
01	R1	11	R11
02	R2	12	Unassigned
03	R3	13	Unassigned
04	R4	14	Unassigned
05	R5	15	Unassigned
06	R6	16	Unassigned
07	IVL Register-Left Bank I/O address register. Used only as a destination.	17	IVR Register-Right Bank I/O address register. Used only as a destination.

a. Register Specification



20_8-27_8 is used to specify the least significant bit of a variable length field within the I/O Port previously selected by the IVL register. The length of the field is determined by R/L.

OCTAL VALUE	
20	Field within previously selected Port; position of LSB = 0
21	Field within previously selected Port; position of LSB = 1
22	Field within previously selected Port; position of LSB = 2
23	Field within previously selected Port; position of LSB = 3
24	Field within previously selected Port; position of LSB = 4
25	Field within previously selected Port; position of LSB = 5
26	Field within previously selected Port; position of LSB = 6
27	Field within previously selected Port; position of LSB = 7

b. Left Bank I/O Field Specification

30_8-37_8 is used to specify the least significant bit of a variable length field within the I/O Port previously selected by the IVR Register. The length of the field is determined by R/L.

OCTAL VALUE	
30	Field within previously selected Port; position of LSB = 0
31	Field within previously selected Port; position of LSB = 1
32	Field within previously selected Port; position of LSB = 2
33	Field within previously selected Port; position of LSB = 3
34	Field within previously selected Port; position of LSB = 4
35	Field within previously selected Port; position of LSB = 5
36	Field within previously selected Port; position of LSB = 6
37	Field within previously selected Port; position of LSB = 7

c. Right Bank I/O Field Specification

Table 5 S AND D FIELD OCTAL ASSIGNMENTS

©IC MASTER 1978

R/L Field (3-Bit Field)

The R/L field performs one of two functions, specifying either a field length (L) or a right rotation (R). The function it specifies for a given instruction depends upon the contents of the S and D fields:

A. When both S and D specify registers, the R/L field is used to specify a right rotation of the data specified by the S field. (Rotation occurs on the bus and not in the source register.) The register source data is right rotated within one instruction cycle time independent of the number of bit positions specified in the R/L field.
B. When either or both the S and D fields specify a variable length I/O data field, the R/L field is used to specify the length of that data field.
C. R/L field assignments are shown in Table 6.

R/L FIELD OCTAL VALUE	SPECIFICATION
0	Field Length = 8 Bits
1	Field Length = 1 Bit
2	Field Length = 2 Bits
3	Field Length = 3 Bits
4	Field Length = 4 Bits
5	Field Length = 5 Bits
6	Field Length = 6 Bits
7	Field Length = 7 Bits

Table 6 R/L FIELD OCTAL ASSIGNMENTS

I Field (5/8-Bit Field)

The I field is used to load a literal value (contained in the instruction) into a register, or a variable I/O data field, or to modify the low order bits of the Program Counter.

The length of the I field is based on the S field in XEC, NZT, and XMIT instructions, as follows:

A. When S specifies a register, the literal I is an 8-bit field (Type III format).
B. When S specifies variable I/O data field, the literal I is a 5-bit field (Type IV format).

A Field (13-Bit Field)

The A field is a 13-bit Program Storage address field. This allows the 8X300 to directly address 8192 instructions.

REGISTER OPERATIONS

When a register is specified as the source and a variable I/O data field is specified as the destination, the low order bits of the results of the instructions MOVE, ADD, XOR are merged with the original destination data.

When an I/O data field of 1 to 8 bits is specified as the source, and a register as the destination, the 8-bit result of the operations MOVE, ADD, AND, XOR is stored in the register. The operations ADD, AND, XOR actually use the I/O data field (1 to 8 bits) with leading zeros to obtain 8-bit source data for use with the 8-bit AUX data during the operation.

IVL and IVR are write-only pseudo registers, and therefore can be specified as destination fields only. Operations involving IVL and IVR as sources are not possible. For example, it is not possible to increment IVR or IVL in a single instruction, and the contents of IVL or IVR cannot be transferred to a working register, or I/O Port.

The OVF (Overflow) Register can only be used as a source field; it is set or reset *only* by the ADD instruction.

ADDRESSING DATA ON THE INTERFACE VECTOR

I/O data fields are implemented via general purpose 8-bit I/O registers called Interface Vector (IV) Bytes. The IV registers serve to select IV bytes. In order for an instruction to access (read or write) an I/O data field, the address must be output to the IVL or IVR registers.

Thus, two instructions are required to operate on an Interface Vector byte.

```
XMIT    ADDRESS, IVL
MOVE    LB, RB
```

Each of the two IV registers (IVL and IVR) may be set to select an IV byte, therefore two I/O ports may be active at one time—one on the Right Bank (IVR) and one on the Left Bank (IVL). Data may be input and output in one instruction following the selection of IV bytes:

```
XMIT    ADDRESS1, IVL·
XMIT    ADDRESS2, IVR
ADD     LB, RB
```

Once the IV byte is selected (addressed) it will remain selected until another address is output to the same IV register. Since an IV register (IVL, IVR) can be used only as a destination field of an instruction, any instruction sending data to IVL or IVR can be used to select an IV byte.

From the user's standpoint, however, all IV byte outputs can be read by an external device regardless of whether they are selected or not.

The address range of IVL and IVR is $0\text{-}255_{10}$.

INSTRUCTION DESCRIPTIONS

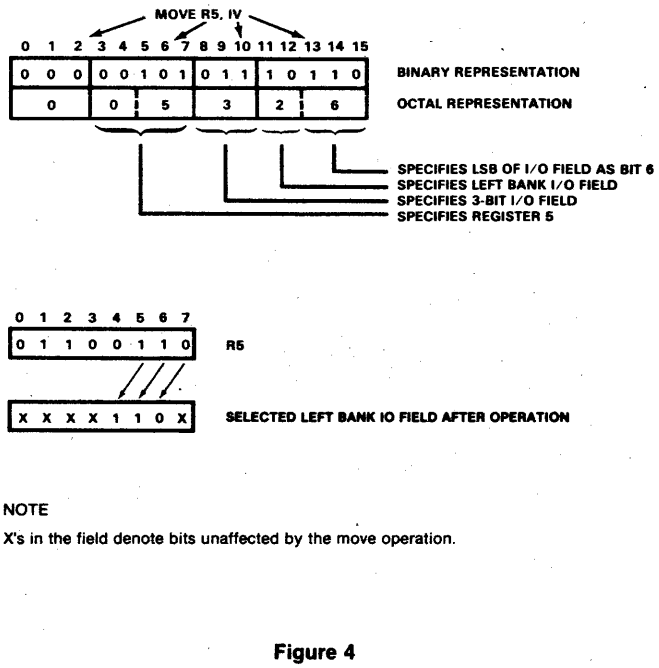
The following instruction descriptions employ MCCAP (the 8X300 Cross Assembly Program) programming notation. This notation varies somewhat from the instruction descriptions provided in Tables 3 through 5. Thus, for example, explicit L field definition, as shown in Table 3 and Table 4 is not required by MCCAP instructions; MCCAP can create appropriate variable field addresses from information contained in Data Declaration statements which may be provided by the programmed at the beginning of his program.

The 8X300 instruction set is described below with examples shown in Figures 4 through 11.

©IC MASTER 1978

MOVE S,D or MOVE S(R),D

Format: Type I, Type II



Operation: (S)➔(D)

Description

Move data. The contents of S are transferred to D; the contents of S are unaffected. If both S and D are registers, R/L specifies a right rotate of the source data before the move. Otherwise, R/L specifies the length of the source and/or destination I/O data field. If the MOVE is between Left Bank and Right Bank I/O field, an 8-bit field must always be moved.

Example

Store the least significant 3 bits of register 5 (R5) in bits 4, 5 and 6 of the I/O Port previously addressed by the IVL register. See Figure 4.

NOTE

X's in the field denote bits unaffected by the move operation.

Figure 4

ADD S,D or ADD S(R),D

Format: Type I, Type II

Operation: (S) + (AUX)⟶D
Carry⟶OVF

Description

Unsigned 2's complement 8-bit addition. The contents of S are added to the contents of the Auxiliary Register. The result is stored in D; OVF is set to the value of the carry. If both S and D are registers, R/L specifies a right rotate of the source (S) data before the operation. Otherwise, R/L specifies the length of the source and/or destination I/O data fields. S and AUX are unaffected unless specified as the destination.

Example

Add the contents of R1 rotated 4 places to AUX and store the result in R3. See Figure 5.

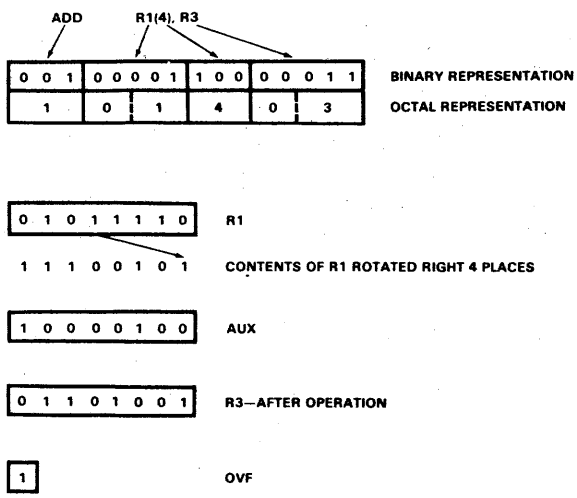


Figure 5

©IC MASTER 1978

AND S,D or AND S(R),D

Format: Type I, Type II

Operation: (S) ∧ (AUX)➔D

Description

Logical AND. The AND of the source field and the Auxiliary Register is stored into the destination. If both S and D are registers, R/L specifies a right rotate of the source (S) data before the AND operation. Otherwise R/L specifies the length of the source and/or destination I/O data fields. S and AUX are unaffected unless specified as a destination.

Example

Store the AND of the selected right bank I/O field and AUX in R4. The right bank data field is called WSBCD and is 4 bits long and located in bits 2, 3, 4 and 5. See Figure 6.

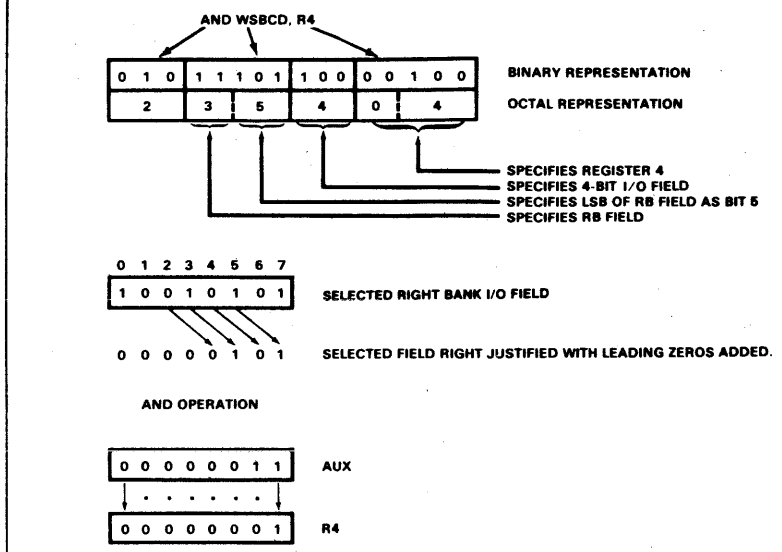

Figure 6

XOR S,D or XOR S(R),D

Format: Type I, Type II

Operation: (S) ⊕ (AUX)➔D

Description

Exclusive-OR. The Exclusive-OR of the source field and the Auxiliary Register is stored in the destination. If both S and D are registers, R/L specifies a right rotate of the source (S) data before the XOR operation. Otherwise R/L specifies the length of the source and/or destination I/O data fields. S and AUX are unaffected unless specified as a destination.

Example

Replace the selected I/O data field with the XOR of the field and AUX. The I/O data field is called STATUS and is 5 bits in length and located in bits 3, 4, 5, 6 and 7 of left bank. See Figure 7.

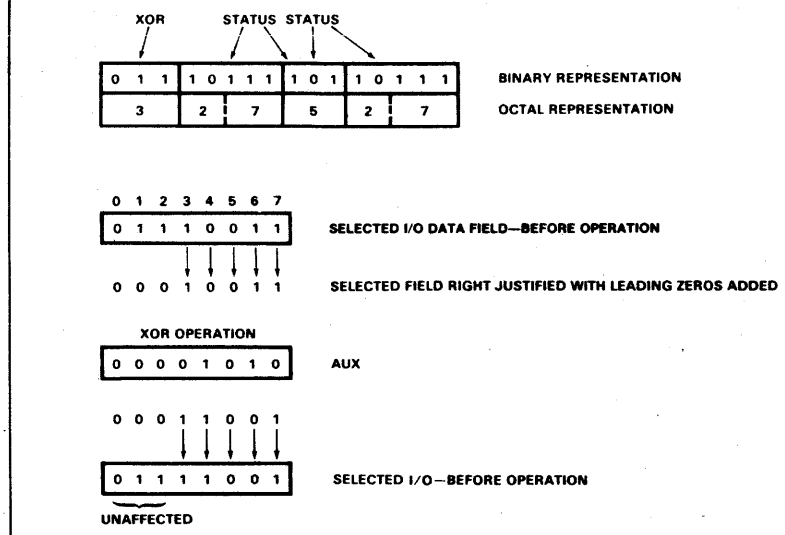

Figure 7

©IC MASTER 1978

XEC I(S)

Format: Type III, Type IV

Operation

Execute instruction at the address specified by the Address Register with lower 5 or 8 bits replaced by (S) + I.

Description

Execute the instruction at the address determined by replacing the low order bits of the Address Register (AR) with the low order bits of the sum of the literal I and the contents of the source field. If S is a register, the low order 8 bits of AR are replaced; if S is an I/O data field, the low order 5 bits of AR are replaced, resulting in an execute range of 256 and 32 respectively. The Program Counter is not affected unless the instruction executed is a JMP or NZT (whose branch is taken).

Example

Execute one of n JMPs in a table of JMP instructions determined by the value of the selected I/O data field on the left bank. The table follows immediately after the XEC instruction and the I/O field is called INTERPT and is a 3-bit field located in bits 4, 5 and 6. See Figure 8.

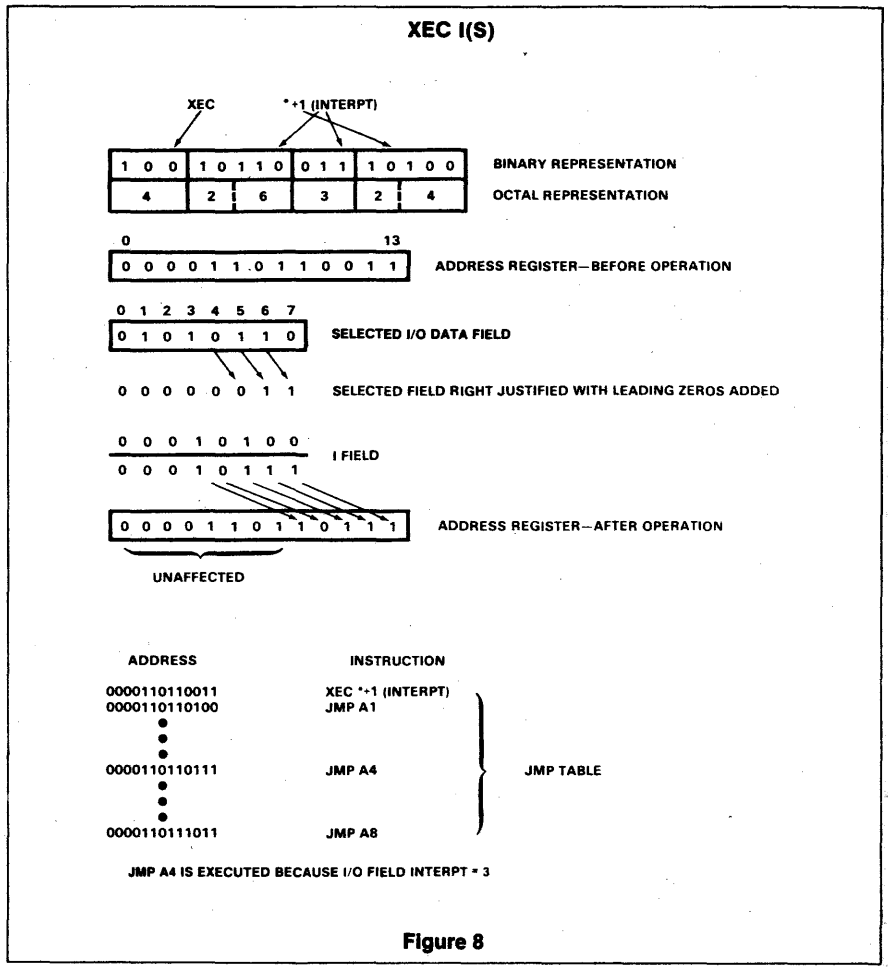

Figure 8

XMIT I,D

Format: Type III, Type IV

Operation: I→(D)

Description

Transmit literal. The literal field I is stored in D. If D is a register, an 8-bit field is transferred; if D is an I/O data field, up to a 5-bit field is transferred.

Example

Store the bit pattern 110 in the selected I/O data field on the right bank. The field name is VALUE and is located in bits 3, 4 and 5. See Figure 9.

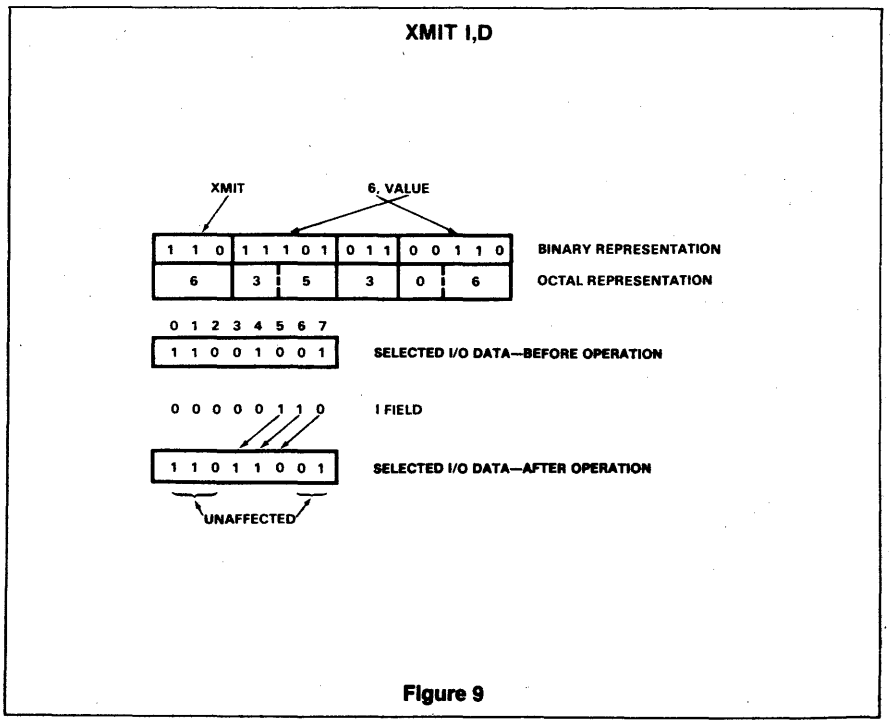

Figure 9

©IC MASTER 1978

NZT S,I

Format: Type III, Type IV

Operation:

Non-Zero Transfer. If (S) ≠ 0, PC offset by I → PC; otherwise PC + 1 → PC.

Description

If the data specified by the S field is non-zero, replace the low order bits of the Program Counter with I. Otherwise, processing continues with the next instruction in sequence. If S is a register, the low order 8 bits of the PC are replaced; if S is an I/O data field, the low order 5 bits of the PC are replaced, resulting in an NZT range of 256 and 32 respectively.

Example

Jump to Program Address ALPHA if the selected right bank I/O field is non-zero. The field name is OVERFLO and it is a 1-bit field located in bit 3. See Figure 10.

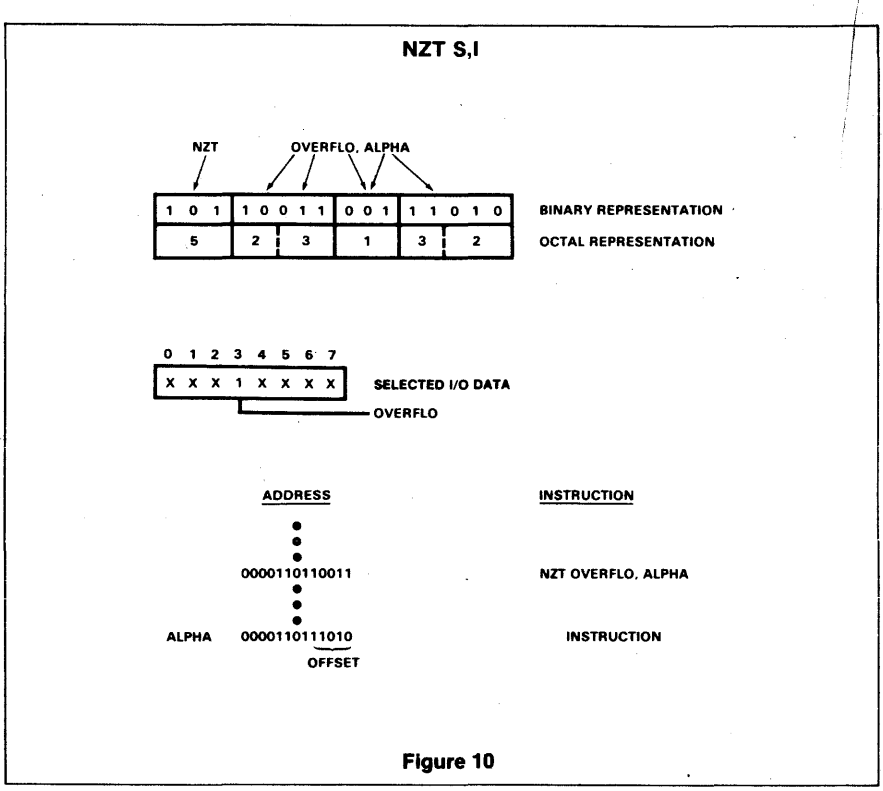

Figure 10

JMP A

Format: Type V

Operation: A → PC

Description

The literal value A is placed in the Program Counter and Address Register, and processing continues at location A. A has a range of 0-17777$_8$ (0-8191).

Example

Jump to location ALPHA (0000101110001). See Figure 11.

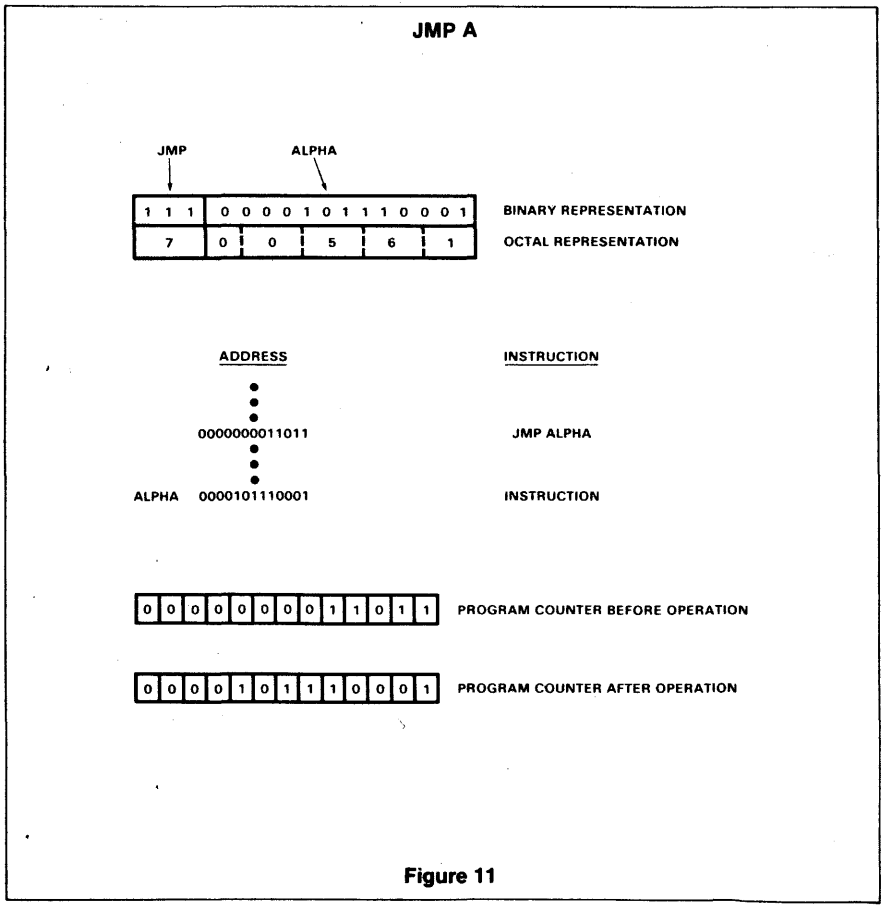

Figure 11

SYSTEM DESIGN USING THE 8X300 MICROCONTROLLER

Designing hardware around the 8X300 Interpreter reduces to selecting a program storage devicer (ROM, PROM, etc.), selecting I/O devices (IV byte, multiplexers, RAM, etc.), selecting clock mode (system driven or crystal controlled) and interfacing the Microcontroller to these components.

A specific example of a control system using the 8X300 Microcontroller is shown in Figure 12. Only 8 components—four 8T32 I/O Ports, one 82S208 RAM, two 82S215 ROMs, and an 8X300 are required to build this system which contains 512 words of program storage, 32 TTL I/O connection points, 256 bytes of working storage, and operates at a 250ns instruction cycle time.

Halt, Reset Signals

$\overline{\text{HALT}}$:
A low level at the $\overline{\text{HALT}}$ input stops internal operation of the Microcontroller at the start of the next instruction after $\overline{\text{HALT}}$ is applied (quarter cycle after MCLK). Since $\overline{\text{HALT}}$ is sampled at the start of each instruction cycle it is possible to prevent a cycle by applying $\overline{\text{HALT}}$ early in that cycle. $\overline{\text{HALT}}$ does not inhibit MCLK or affect any internal registers. Normal operation begins with the next complete cycle after the $\overline{\text{HALT}}$ input goes high.

$\overline{\text{RESET}}$:
A low level at the $\overline{\text{RESET}}$ input sets the program counter and address register to zero. While $\overline{\text{RESET}}$ is low MCLK is inhibited. If $\overline{\text{RESET}}$ is applied during the last 2 quarter cycles, the MCLK during that cycle may be shortened. $\overline{\text{RESET}}$ should be applied for 1 full instruction cycle time to assure proper operation. When $\overline{\text{RESET}}$ input goes high an MCLK occurs prior to the resumption of normal processing. $\overline{\text{RESET}}$ does not affect the other internal registers.

SYSTEM TIMING

In systems with fast instruction cycle times, most Microcontroller delays are strictly determined by internal gate propagation delays.

EXAMPLE OF CONTROL SYSTEM

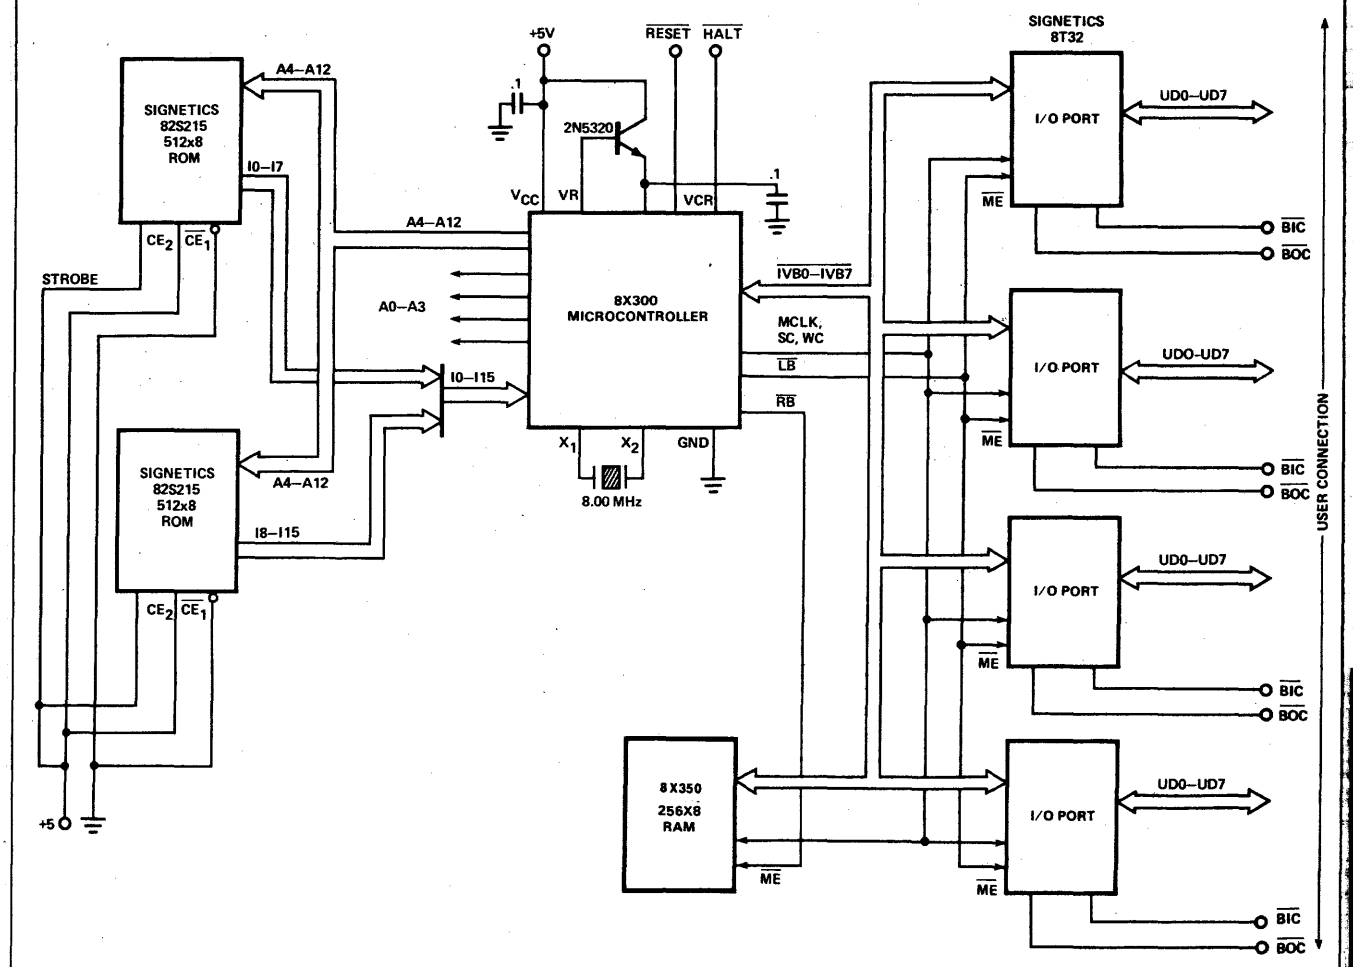

Figure 12

©IC MASTER 1978

Since some events are constrained to occur in certain quarter cycles, as system cycle times become slower, the delays will appear to increase due to gating with internal clocks. In the table of AC Electrical Characteristics, 2 columns are used: 1 to denote times which occur due to internal clock intervention and 1 to denote minimum delays for fast cycle times.

When using Signetics 8T32 I/O Ports, selection of instruction cycle time involves calculating the maximum program storage access time. Assuming the instruction is available when MCLK falls, the I/O control lines are stable 35ns later. Signetics 8T32's require another 35ns to disable a previously selected port and enable the desired port (assumes a change in bank signals). A 10ns margin has been added to the 8T32 enable for this evaluation to reflect the fact that most systems will have more capacitive loading than the 50pF test condition in the 8T32 specification and to allow for line delays.

The system instruction cycle time for normal systems such as shown in Figure 12 is determined by Microcontroller propagation delays, program storage access time, and port output enable times. Instruction cycle time is normally constrained by one or more of the following conditions:

1. Instruction to LB/RB (input phase) and I/O Port output enable:
   $T_{OE} \leq \frac{1}{2}$ cycle - 55ns (Figure 13).
2. Program storage access time and instruction to LB/RB (input phase) and I/O Port output enable and IV data (input phase) to address ≤ instruction cycle time (Figure 14).
3. Program storage access time and instruction to address ≤ instruction cycle time (Figure 15).

The first constraint can be used to determine the minimum cycle time. Using the inequality 35ns + 35ns ≤ ½ cycle - 55ns implies ½ cycle ≥ 125ns or an instruction time of 250ns.

Program storage access time for a 250ns instruction cycle can be calculated from the second constraint. Noting that the specification for IV data (input phase) to address is 115ns: Program storage access time + 35ns + 35ns + 115ns ≤ 250ns implies program storage access time ≤ 65ns.

The third constraint can be used to verify the maximum program storage access time. Noting that the specification for instruction to address is 185ns: Program storage access time + 185ns ≤ 250ns confirms that program storage access time 65ns is satisfactory.

SYSTEM INSTRUCTION CYCLE TIME

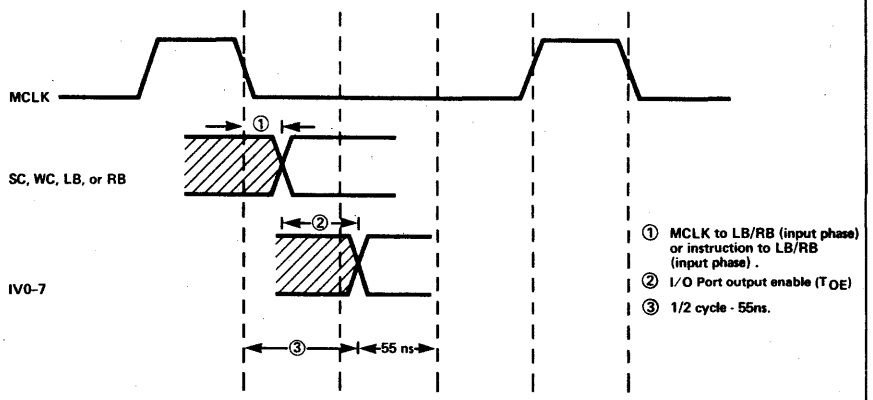

Figure 13

SYSTEM INSTRUCTION CYCLE TIME

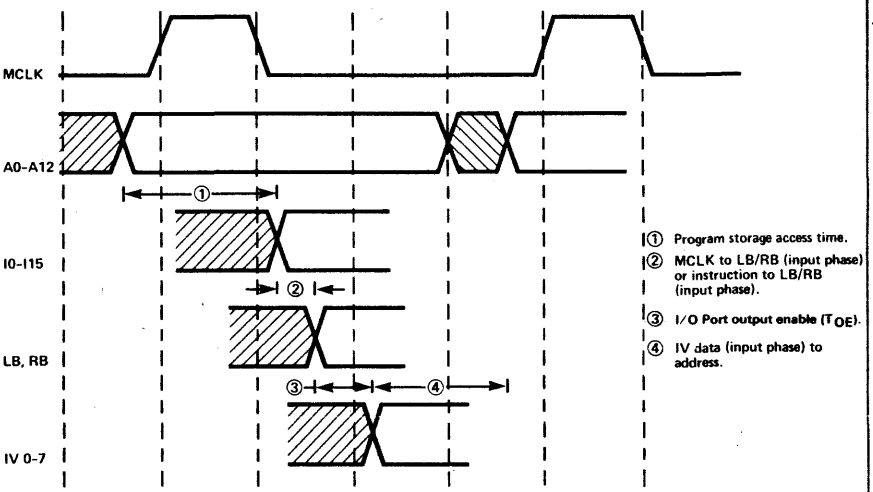

Figure 14

SYSTEM INSTRUCTION CYCLE TIME

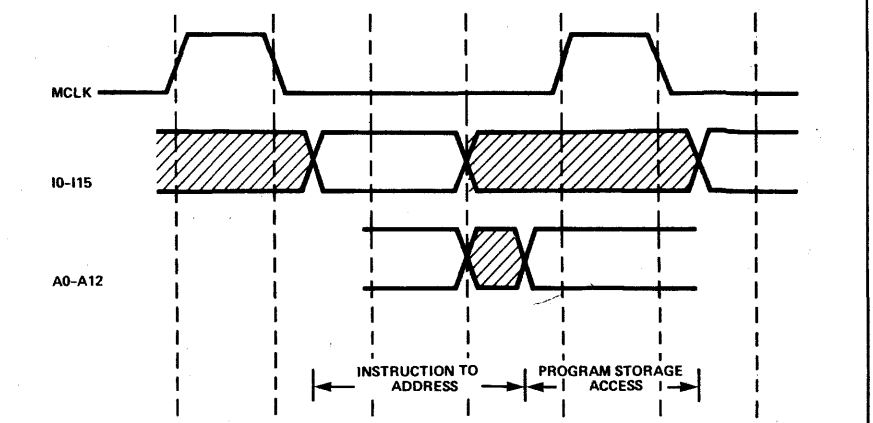

Figure 15

©IC MASTER 1978

System Clock

The Micrcontroller has an integrated oscillator which generates all necessary clock signals. The oscillator is designed to connect directly to a series resonant quartz crystal via pins X1 and X2. The crystal resonant frequency, f, is related to the desired cycle time, T, by the relationship f = 2/T. For a 250ns system, f = 8.00MHz.

Type:	Fundamental mode, series resonant
Impedance at Fundamental:	35 ohms maximum
Impedance at harmonics and spurs:	50 ohms minimum

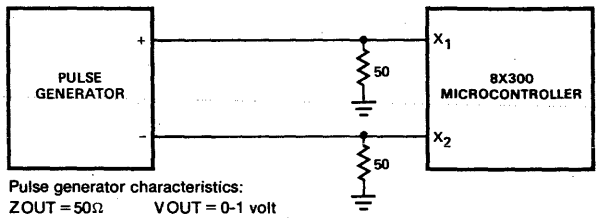

Table 7 CRYSTAL CHARACTERISTICS

In lower speed applications where the cycle time need not be precisely controlled, a capacitor may be connected between X1 and X2 to drive the oscillator. Approximate capacitor values are given in Table 8. If cycle time is to be varied, X1 and X2 should be driven from complementary outputs of a pulse generator. Figure 16 shows a typical configuration. For systems where the Interpreter is to be driven from a master clock the X1 and X2 lines may be interfaced to TTL logic as shown in Figure 17.

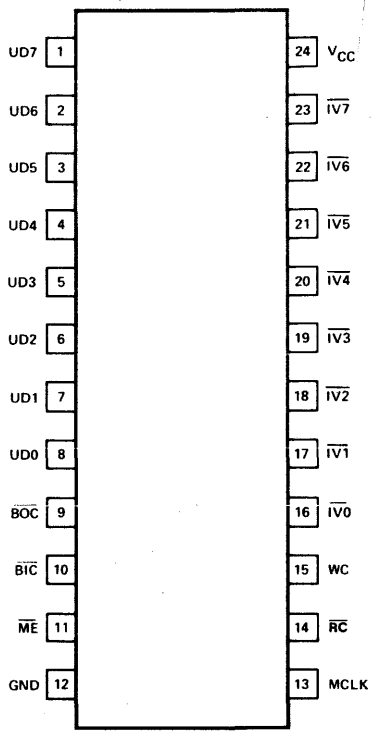
8T31-N/F

DESCRIPTION

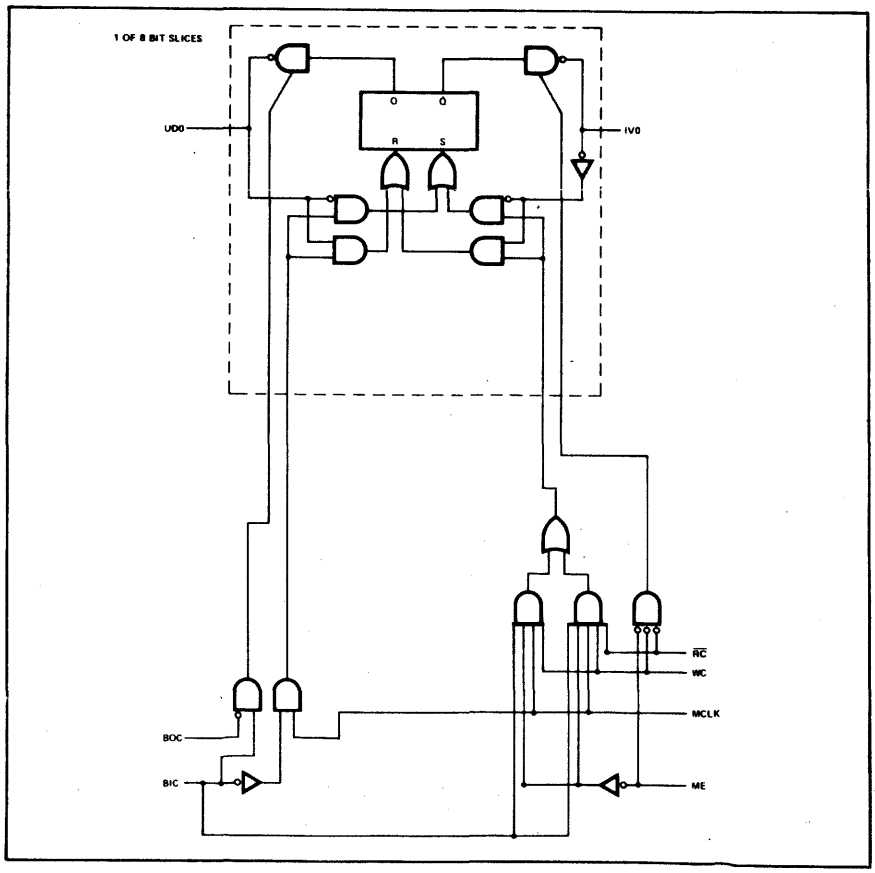
The I/O Port is an 8-bit bidirectional data register designed to function as an I/O interface element in microprocessor systems. It contains 8 clocked data latches accessible from either a microprocessor port or a user port. Separate I/O control is provided for each port. The 2 ports operate independently, except when both are attempting to input data into the I/O Port. In this case, the user port has priority.

A master enable (ME) is provided that enables or disables the μP bus regardless of the state of the other inputs, but has no effect on the user bus.



A unique feature of this family is its ability to start up in a predetermined state. If the clock is maintained at a voltage less than .8V until the power supply reaches 3.5V, the user port will always be all logic 1 levels, while the microprocessor port will be all logic 0 levels.

FEATURES



- **Each device has 2 ports, one to the user, the other to a microprocessor. I/O Ports are completely bidirectional**
- **Ports are independent, with the user port having priority for data entry**
- **User data input synchronous**
- **The user data bus is available with tri-state (8T32, 8T36) or open collector (8T33, 8T35) outputs**
- **At power up, the user port outputs are high**
- **Tri-state TTL outputs for high drive capability**
- **Directly compatible with the 8X300 Microcontroller**
- **Operates from a single 5V power supply over a temperature range of 0°C to +70°C**

L	X	H	H	H	Input Data
X	H	L	X	X	Inactive
X	X	H	X	L	Inactive
H	X	X	X	X	Inactive

Table 2 MICROPROCESSOR PORT CONTROL FUNCTION

USER DATA BUS CONTROL

The activity of the user data bus is controlled by the BIC and BOC inputs as shown in Table 1.

The user data input is a synchronous function with MCLK. A low level on the BIC input allows data on the user data bus to be written into the data latches only if MCLK is at a high level. A low level on the BIC input allows data on the user data bus to be latched regardless of the level of the MCLK input.

To avoid conflicts at the data latches, input from the microprocessor port is inhibited when BIC is at a low level. Under all other conditions the 2 ports operate independently.

MICROPROCESSOR BUS CONTROL

As is shown in Table 2, the activity of the microprocessor port is controlled by the ME, RC, WC and BIC inputs, as well as the state of an internal status latch. BIC is included to show user port priority over the microprocessor port for data input.

BUS OPERATION

Data written into the I/O Port from one port will appear inverted when read from the other port. Data written into the I/O Port from one port will not be inverted when read from the same port.

8T32/8T33/8T35/8T36-F,NA

TYPES

8T32 Tri-State, Synchronous User Port
8T33 Open Collector, Synchronous User Port
8T35 Open Collector, Asynchronous User Port
8T36 Tri-State, Asynchronous User Port

DESCRIPTION

The Addressable I/O Port is an 8-bit bidirectional data register designed to function as an I/O interface element in microprocessor systems. It contains 8 data latches accessible from either a microprocessor port or a user port. Separate I/O control is provided for each port. The 2 ports operate independently, except when both are attempting to input data into the I/O Port. In this case, the user port has priority.

A unique feature of the I/O Port is the way in which it is addressed. Each device has an 8-bit, field programmable address, which is used to enable the microprocessor port. When the SC control signal is high, data at the microprocessor port is treated as an address. If the address matches the I/O Port's internally programmed address, the microprocessor port is enabled, allowing data transfer through it.

The port remains enabled until an address which does not match is presented, at which time the port is disabled (data transfer is inhibited). A Master Enable input (ME) can serve as a ninth address bit, allowing 512 I/O Ports to be individually selected on a bus, without decoding. The user port is accessible at all times, independent of whether or not the microprocessor port is selected.

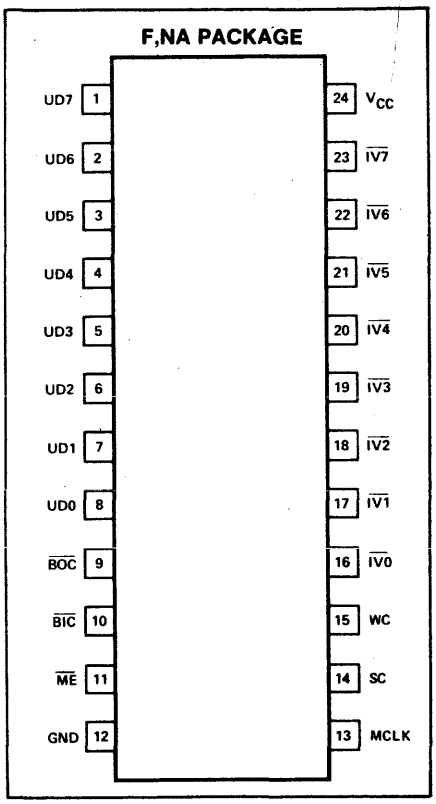
A unique feature of this family is their ability to start up in a predetermined state. If the clock is maintained at a voltage less than .8V until the power supply reaches 3.5V, the user port will always be all logic 1 levels, while the port will be all logic 0 levels.

ORDERING

The 8T32/33/35/36 may be ordered in preaddressed form. To order a preaddressed device use the following part number format:

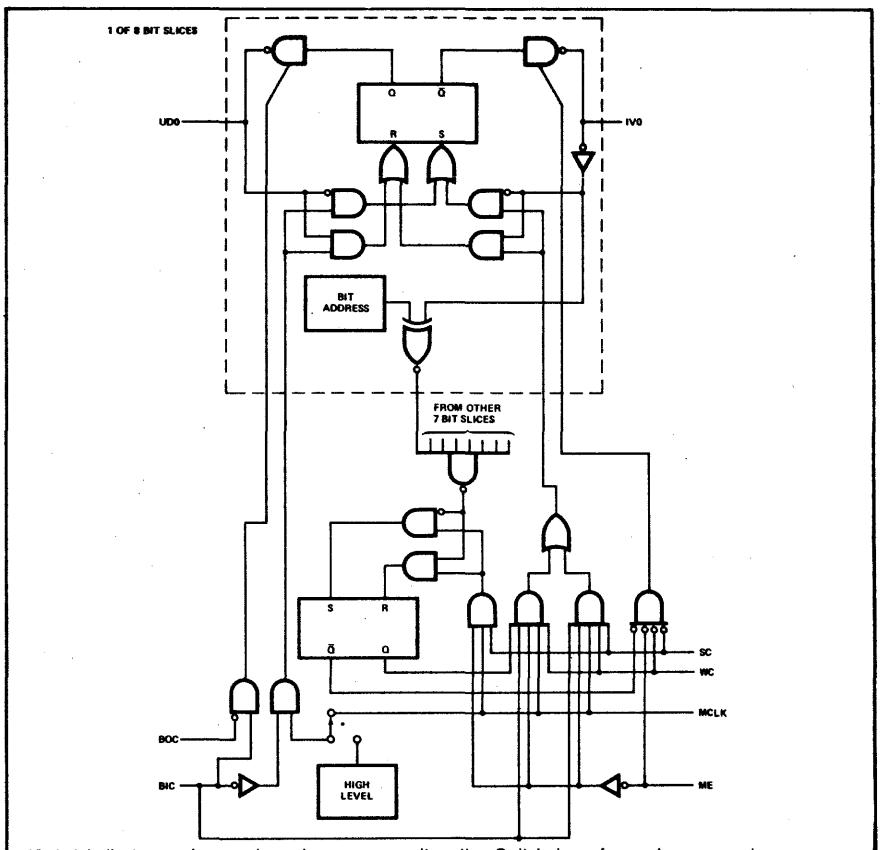
N8TYY-XXX P

- -P = F Ceramic package, NA Plastic package
- XXX = Any address from 000 through 255 (decimal) - 256 available addresses
- YY = I/O Port version (32, 33, 35, 36)



A stock of 8T32s and 8T36s with addresses 1 through 10 will be maintained. A small quantity of addresses 11 through 50 will also be available with a longer lead time.

FEATURES



- **A field-programmable address allows 1 of 512 I/O Ports on a bus to be selected, without decoders.**
- **Each device has 2 ports, one to the user, the other to a microprocessor.**
- **Completely bidirectional.**
- **Ports are independent, with the user port having priority for data entry.**
- **A selected I/O Port de-selects itself when another I/O Port address is sensed.**
- **User data input available as synchronous (8T32, 8T33) or as asynchronous (8T35, 8T36) function.**
- **The user data bus is available with tri-state (8T32, 8T36) or open collector (8T33, 8T35) outputs.**
- **At power up, the I/O Port is not selected and the user port outputs are high.**
- **Tri-state TTL outputs for high drive capability.**
- **Directly compatible with the 8X300 Microcontroller.**
- **Operates from a single 5V power supply over a temperature range of 0° C to 70° C.**

signetics

USER DATA BUS CONTROL

The activity of the user data bus is controlled by the BIC and BOC inputs as shown in Table 1.

For the 8T32 and 8T33, user data input is a synchronous function with MCLK. A low level on the BIC input allows data on the user data bus to be written into the data latches only if MCLK is at a high level. For the 8T35 and 8T36, user data input is an asynchronous function. A low level on the BIC input allows data on the user data bus to be latched regardless of the level of the MCLK input. Note that when 8T35 or 8T36 are used with the 8X300 Microcontroller care must be taken to insure that the Microprocessor bus is stable when it is being read by the 8X300 Microcontroller.

To avoid conflicts at the Data Latches, input from the Microprocessor Port is inhibited when BIC is at a low level. Under all other conditions the 2 ports operate independently.

MICROPROCESSOR BUS CONTROL

As is shown in Table 2, the activity of the microprocessor port is controlled by the ME, SC, WC and BIC inputs, as well as the state of an internal status latch. BIC is included to show user port priority over the microprocessor port for data input.

Each I/O Port's status latch stores the result of the most recent I/O Port select; it is set when the I/O Port's internal address matches the Microprocessor Bus. It is cleared when an address that differs from the internal address is presented on the Microprocessor Bus.

In normal operation, the state of the status latch acts like a master enable; the microprocessor port can transfer data only when the status latch is set.

When SC and WC are both high, data on the Microprocessor Bus is accepted as data, whether or not the I/O Port was selected. The data is also interpreted as an address. The I/O Port sets its select status if its address matches the data read when SC and WC were both high; it resets its select status otherwise.

BUS OPERATION

Data written into the I/O Port from one port will appear inverted when read from the other port. Data written into the I/O Port from one port will not be inverted when read from the same port.

ADDRESS PROGRAMMING

The I/O Port is manufactured such that an address of all high levels (>2V) on the Microprocessor Bus inputs matches the Port's internal address. To program a bit so a low-level input (<0.8V) matches, the following procedure should be used:

1. Set all control inputs to their inactive state (BIC = BOC = ME = V_{CC}, SC = WC = MCLK = GND). Leave all Microprocessor Bus I/O pins open.
2. Raise V_{CC} to 7.75V ± .25V.
3. After V_{CC} has stabilized, apply a single programming pulse to the user data bus bit where a low-level match is desired. The voltage should be limited to 18V; the current should be limited to 75mA. Apply the pulse as shown in Figure 1.
4. Return V_{CC} to 0V. (Note 1).
5. Repeat this procedure for each bit where a low-level match is desired.
6. Verify that the proper address is programmed by setting the Port's status latch (IV0-IV7 = desired address, ME = WC = L, SC = MCLK = H). If the proper address has been programmed, data presented at the μP bus will appear inverted on the user bus outputs. (Use normal V_{CC} and input voltage for verification.)

After the desired address has been programmed, a second procedure must be followed to isolate the address circuitry. The procedure is:

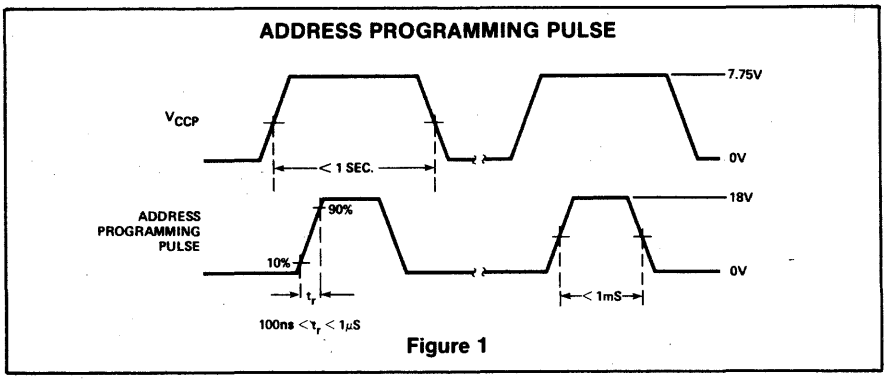

Figure 1

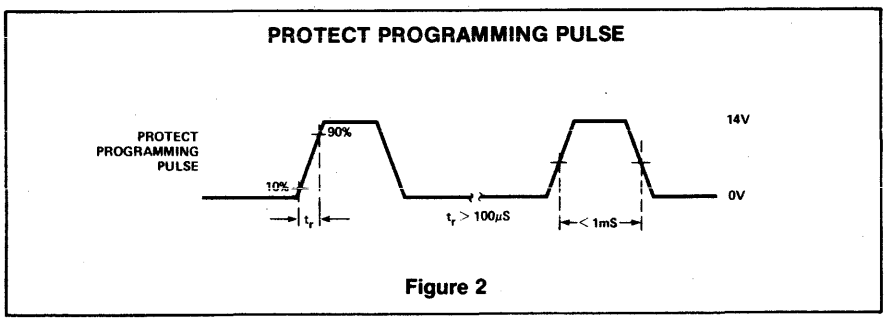

Figure 2

1. Set V_{CC} and all control inputs to 0V. (V_{CC} = BIC = BOC = ME = SC = WC = MCLK = 0V). Leave all Microprocessor Bus I/O pins open.
2. Apply a protect programming pulse to every user data bus pin, one at a time. The voltage should be limited to 14V; the current should be limited to 150mA. Apply the pulse as shown in Figure 2.
3. Verify that the address circuitry is isolated by applying 7V to each user data bus pin and measuring less than 1mA of input current. The conditions should be the same as in step 1 above. The rise time on the verification voltage must be slower than 100μs.

APPLICATIONS

Figure 3 shows some of the various ways to use the I/O Port in a system. By controlling the BIC and BOC lines, the device may be used for the input and output of data, control, and status signals. I/O Port 1 functions bidirectionally for data transfer and I/O Port 2 provides a similar function for discrete status and control lines. I/O Ports 3 and 4 serve as dedicated output and input ports, respectively.

8T32 APPLICATIONS

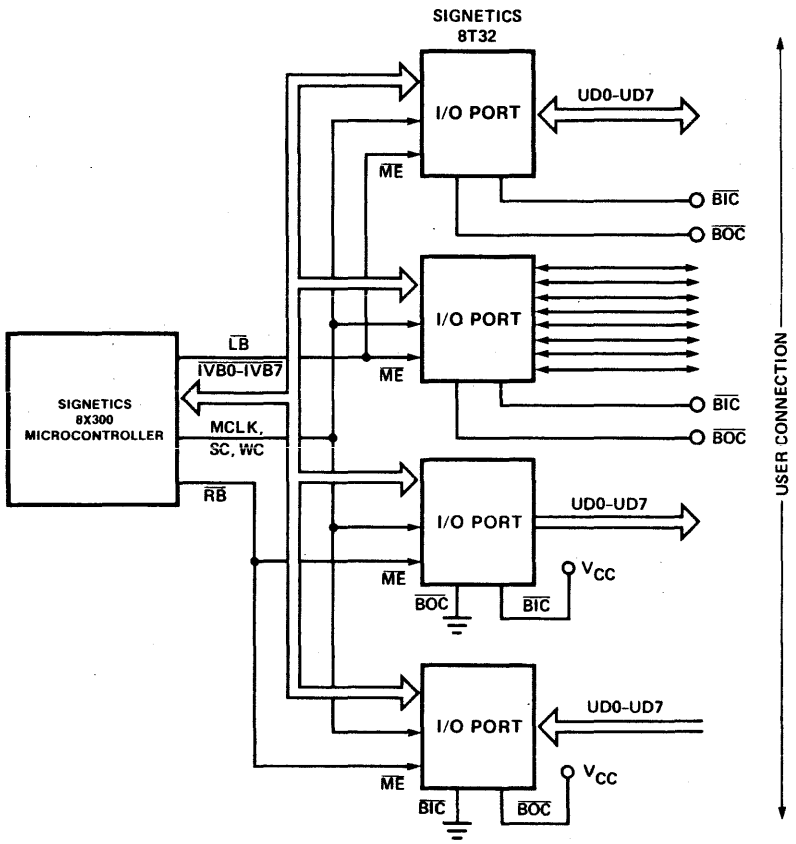

Figure 3

©IC MASTER 1978

PRELIMINARY SPECIFICATION 8T39-I,XL

DESCRIPTION

The Bus Expander is specifically designed to increase the I/O capability of 8X300 systems previously limited by fanout considerations. The bus expander serves as a buffer between the 8X300 and blocks of I/O devices. Each bus expander can buffer a block of 16 I/O ports while only adding a single load to the 8X300.

FEATURES

- **15ns max propagation delay**
- **Bidirectional**
- **Three-state outputs on both ports**
- **Pre-programmed address range**

APPLICATIONS

The 8T39 Bus Expander is designed to be used with the 8X300 microprocessor to allow increased I/O capability in those systems previously limited by fanout considerations. Figure 1 shows a typical arrangement of the bus expander in an 8X300 system. Each expander services I/O ports whose address is within the range of the expander. Other I/O ports or working storage may be directly connected to the bus as shown.

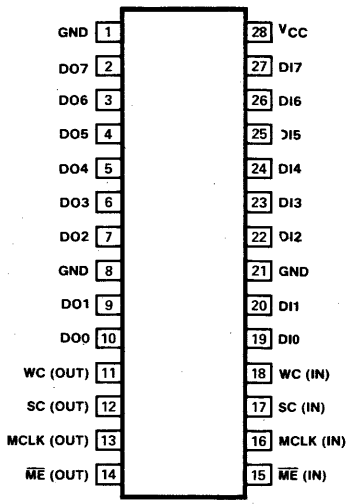
The bus expander is not limited to use with the 8X300, but may be applied in any system which uses a combined address/data bus.

8T39 ADDRESSING

During normal operation of the 8X300 when an I/O port address is being sent on the IV Bus (SC is high), the I/O port will examine all eight bits of the microprocessor bus for an address compare. Since the 8T39 is used to buffer blocks of I/O ports, only the four most significant bits are examined by the 8T39 for an address compare.

Note that redundant addresses are not programmed into separate devices. Rather, a discrete device (such as the 8T39-03) may be wired for any address requiring two 1 bits and two 0 bits in the address. The various address ranges for this same device are obtained by permuting the high order (DI0 and DO0 are MSB) data lines accordingly. Both input and output lines must be redefined in order to maintain data and address integrity on the extended bus. Table 1 summarizes the 8T39 addressing.

Address functions are specified with the convention that bit 0 is the MSB and bit 7 is the LSB. The DI microprocessor bus address decoding is active low.



FUNCTIONAL DESCRIPTION

The Bus Expander contains eight sets of non-inverting bidirectional tri-state drivers for the bus data bits, four non-inverting unidirectional drivers for I/O port control, and necessary control logic. The control logic is required to maintain the proper directional transfer of bus data as dictated by the states of the I/O port control signals and the currently enabled I/O port. Each bus expander is programmed during manufacturing to respond to a specific block of I/O port addresses. Only I/O ports with addresses in the range of a given bus expander may be connected to that expander. A bus expander may be used on either left bank or right bank. Multiple expanders on the same bank must have different address ranges; however, expanders with the same address range can be connected if they are on different banks. Systems may be configured with I/O ports connected directly to the 8X300, as well as I/O ports connected through a bus expander; however, no unbuffered I/O port may have an address within the span of a bus expander on the same bank.

Addition of bus expanders may impact system cycle time due to the added delay in the data path. For the purposes of calculating allowable cycle time as described in the 8X300 data sheet, the bus expander delays may be considered additive to the I/O port delays so that a buffered I/O port simply appears as a slower I/O port.

NE5018-F,N

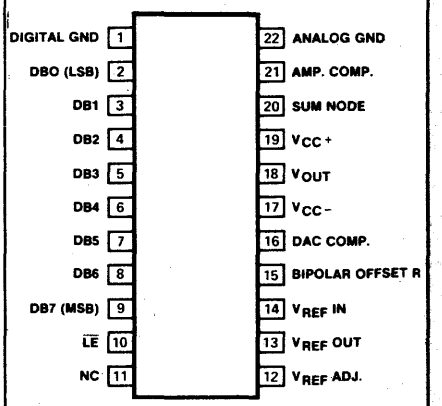
DESCRIPTION

The NE5018 is a complete 8-bit digital to analog converter subsystem on one monolithic chip. The data inputs have input latches,controlled by a latch enable pin. The data and latch enable inputs are ultra-low loading for easy interfacing with all logic systems. The latches appear transparent when the $\overline{LE}$ input is in the low state. When $\overline{LE}$ goes high, the input data present at the moment of transition is latched and retained until $\overline{LE}$ again goes low. This feature allows easy compatibility with most microprocessors.

The chip also comprises a stable voltage reference (5V nominal) and a high slew rate buffer amplifier. The voltage reference may be externally trimmed with a potentiometer for easy adjustment of full scale, while maintaining a low temperature co-efficient.

The output of the buffer amplifier may be offset so as to provide bipolar as well as unipolar operation.

FEATURES



- **8-bit resolution**
- **Input latches**
- **Low-loading data inputs**
- **On-chip voltage reference**
- **Output buffer amplifier**
- **Accurate to ± 1/2 LSB**
- **Monotonic to 8 bits**
- **Amplifier and reference both short-circuit protected**
- **Compatible with 2650, 8080 and many other μP's.**

APPLICATIONS

- **Precision 8-bit D/A converters**
- **A/D converters**
- **Programmable power supplies**
- **Test equipment**
- **Measuring instruments**
- **Analog-digital multiplication**

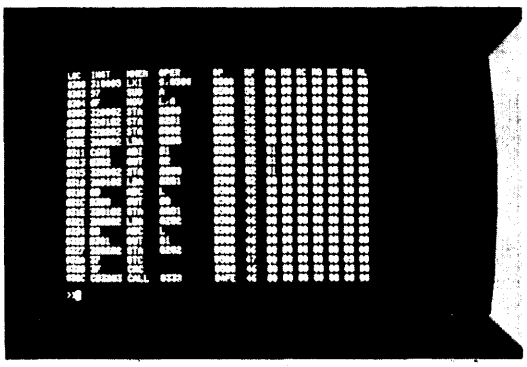
PRODUCT

PROGRAM DESIGN

Prepare detailed flow charts for optimum microprocessor operation.

CODE

Code detailed flow charts into assembly language using 8002 Microprocessor Lab's editing capabilities.



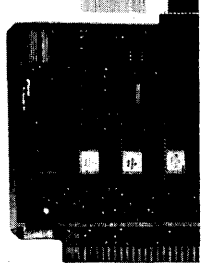
Software creation is made easy with the 8002 Microprocessor Lab's editing capabilities. TEKDOS maintains files while you concentrate on entering and revising the program.

ASSEMBLE

Assemble coded programs into machine language using 8002 Microprocessor Lab's universal assembler processor.

DEBUG

Trace and debug programs using 8002 or 8001 program emulation and debugging capabilities.



The software is executed and debugged on the prototype with the addition of the appropriate emulator processor. This dynamic trace capability enables you to trace program execution, set breakpoints, and examine memory and register contents.

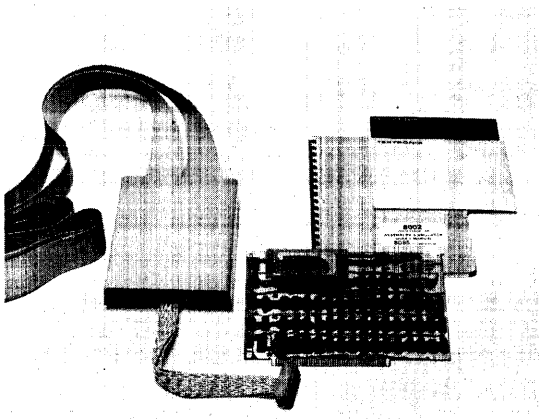
8002 Microprocessor Lab

- **Multiple Microprocessor Support**
- **A Complete Software Development System**
- **Real-Time Trace Option**

The 8002 Microprocessor Lab consists of the 8002 Mainframe; the dual flexible disc unit; a system terminal (TEKTRONIX CT8100 or CT8101 recommended); and two sets of assembler software for two different microprocessors, chosen from the microprocessors supported at time of purchase. An emulator processor module for each microprocessor the system supports, and its associated prototype control probe, are offered as options.

The 8002 Microprocessor Lab is a complete software development system for the design of microprocessor-based products. A key feature is its ability to support many microprocessor chips, including the Intel 8085 and 8080, Motorola 6800, Texas Instruments 9900, and Zilog Z-80. The system will support other microprocessors in the future.



In addition to multiple microprocessor support, the 8002 offers a superior operating system and powerful text editor, assembler, and debugging programs; three optional levels of emulation for software debugging, partial and full emulation; and a real-time prototype analyzer option with all the capabilities of a microprocessor analyzer plus eight channels of external input.

Software development and debugging

In a typical design sequence, software is developed using all the resources of TEKDOS, the disc-operating system software for the 8002 Microprocessor Lab. TEKDOS performs flexible disc and file utility functions, data transfer functions, and system/peripheral device control functions. In addition to relieving the user of these housekeeping chores, TEKDOS also supervises the text editor, assembler, and linker programs and the optional emulation support, debugging system and PROM programming routines.

Program entry and editing may be accomplished module by module. The line-oriented text editor provides 150 60-character lines of buffer workspace, and offers several convenience features for preparing, correcting, and modifying the program quickly and easily. The macro assembler allows a multiple-step routine to be defined by a single command. At the end of each work session, file space is allocated by TEKDOS; duplicate files of important material may be readily created. When program entry has been completed, all program files may be merged with a single TEKDOS command.

The assembler processor, with the appropriate disc inserted in the flexible disc drive, performs program assembly functions for each microprocessor supported by the 8002.

After an error-free assembly listing has been obtained, the resulting object code may be executed in system emulation (mode 0) on the optional emulator processor. The emulator processor is identical to the microprocessor that will finally be installed in the user's prototype. Execution is performed under control of the debugging system; during execution, program steps can be traced, software breakpoints can be set, and memory can be examined and changed as required. Should an error be discovered, that portion of the program can be corrected at the source level using the text editor. It can then be reassembled and executed again. This procedure continues until the program is clean.

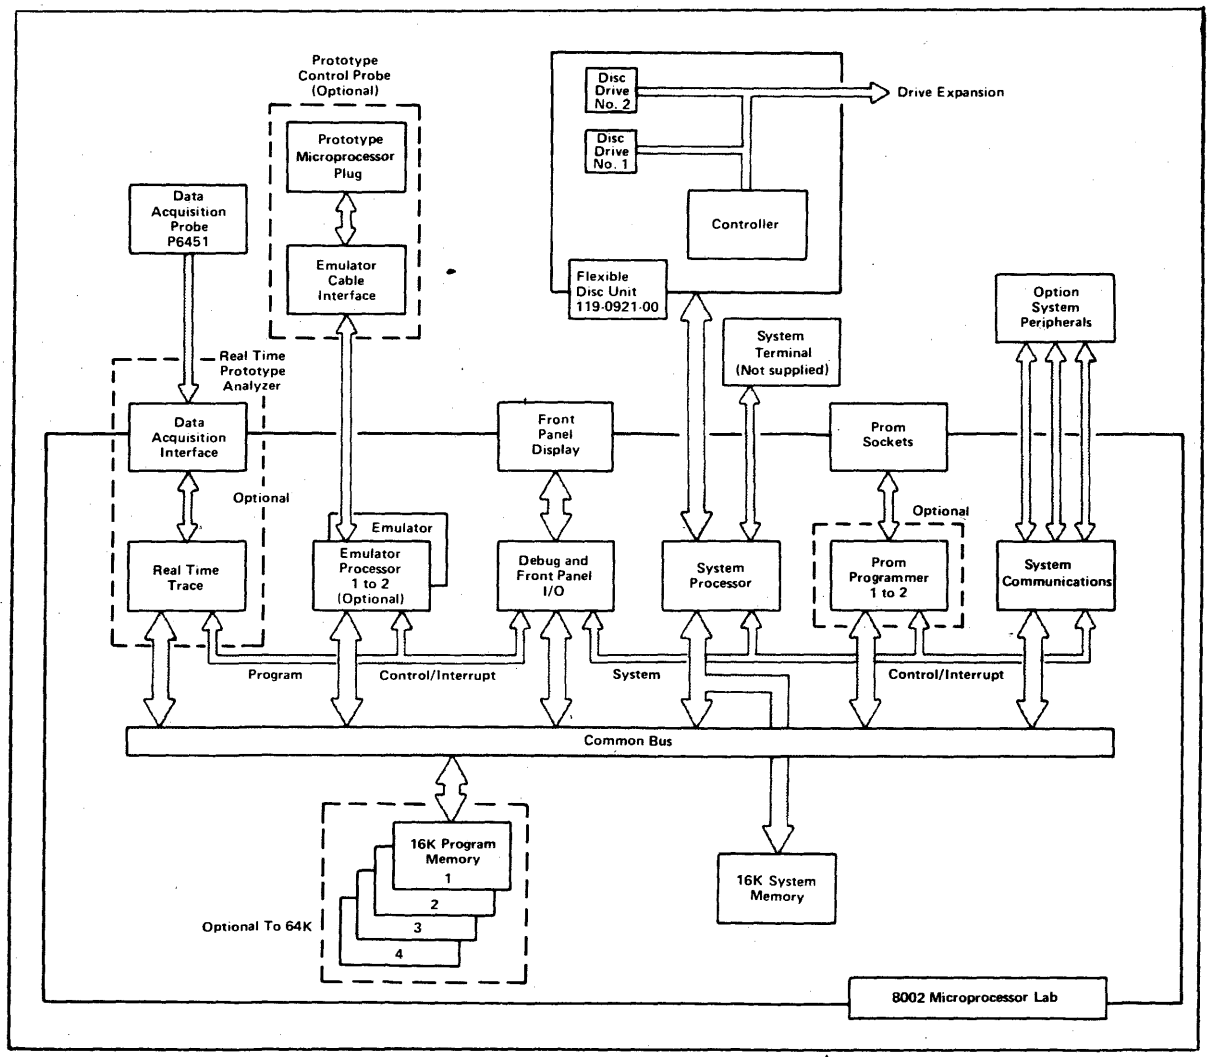
©IC MASTER 1978

Partial and Full Emulation

After the software has been partially debugged, it may be exercised on the prototype circuitry in the partial emulation mode (mode 1). During partial emulation, control may be released from the 8002 to the prototype in stages. The developmental software runs using 8002 memory space and prototype I/O and clock. The 8002 memory mapping feature allows memory to be gradually mapped over to the prototype by any combination of 128-byte address blocks. Throughout partial emulation, the user has access to prototype circuitry through the debugging system, which enables him, as before, to trace, set breakpoints, examine and change memory and register contents.

In full emulation (mode 2) the program is run on the now stand-alone prototype, but program execution is still under complete control of the debugging system. All I/O and timing functions are directed by the prototype; all memory has been mapped over to the prototype; and only the prototype control probe is still in place, emulating the target microprocessor. Although the prototype is effectively freestanding, then, the user may still direct program activity from the 8002.

Hardware Trace Option



The optional real-time prototype analyzer enables the user to dynamically monitor the prototype address bus, data bus, and up to eight other locations on the prototype circuit board. Prototype activity is monitored at full speed, without stopping or slowing up the working microprocessor. This enables the designer to locate critical timing problems and hardware/software sequence problems during partial and full emulation.

In summary, then, each of the three emulation modes supports a specific phase of the product development cycle. Beginning with program entry, editing, and assembly, the designer proceeds from software debugging (mode 0), to the sequential integration of program and circuit (mode 1), to the final integration and test of the stand-alone product (mode 2). The real-time prototype analyzer enhances modes 1 and 2 by allowing the user to monitor and access prototype activity in real time.

8002 CHARACTERISTICS

The 8002 Microprocessor Lab is a modular system whose mainframe houses up to 20 plug-in circuit boards. The system includes System Processor, Debug and Front-Panel I/O; System Memory; Program Memory; System Communications; and Assembler Processor modules. A system terminal is necessary but not supplied.

Available as options are an Emulator Processor module and associated Prototype Control Probe for the microprocessor of choice to support three progressive levels of emulation. The Real-Time Prototype Analyzer module, additional 16K byte Program Memory modules, and ePROM Programmer modules for the 1702 or 2704/2708 are also available as options. Optional peripherals include the TEKTRONIX CT8100 Crt Terminal, CT 8101 TTY Terminal, and LP8200 Line Printer.

8002 DUAL FLEXIBLE DISC CHARACTERISTICS

Flexible Disc Unit

The Flexible Disc Unit consists of two disc drives, a controller, and power supplies. The two disc drives are designated as drive 0 and drive 1. Drive 0 is the default system drive. System programs are placed in this drive, including disc-operating system programs, the text editor, and the debugging routines peculiar to a specific Emulator Processor. Drive 1 may be used for storing user files, for modifying user files, or as a scratch data area. Drive 1 can also be designated as the system drive.

Disc Organization

Each disc contains 77 concentric tracks. Each quarter track, or block, is split into eight sectors, and each sector can contain 128 bytes. Due to directory limitations, a maximum of 72 files can be contained on one disc. The disc operating system reserves track 0 for the disc directory; tracks one through four are normally automatically reserved for system programs.

Write Protection

Each disc has a write protect slot. If the slot is covered, the disc is write enabled; if the slot is not covered, the disc is write protected. If an attempt is made to write to a write-protected disc, an error message will be displayed on the appropriate peripheral.

ENVIRONMENTAL CHARACTERISTICS

Temperature	
Operating	+10°C to +35°C (+50°F to +104°F).
Storage	Not available.
Altitude	
Operating	To 15,000 feet max.
Storage	To 50,000 feet max.
Humidity	
Operating	20%-80% relative noncondensing.
Storage	Not available.

PHYSICAL CHARACTERISTICS

Size	
Height	27 cm (10.5 in)
Width	44 cm (17.5 in)
Length	60 cm (23.62 in)
Weight	38.63 Kg (85 lb)

ELECTRICAL CHARACTERISTICS

8001 Microprocessor Lab

- **Multiple Microprocessor Support**
- **A Total Hardware Debugging Environment**
- **Real-Time Trace Option**

The 8001 Microprocessor Lab consists of the 8001 Mainframe; a system terminal (TEKTRONIX CT8100 or CT8101 recommended); and a Microprocessor Support Package for the microprocessor selected. A support package includes an emulator ROM, an emulator processor, and a prototype control probe.

The 8001 Microprocessor Lab is a total hardware debugging environment for the design of microprocessor-based products. A key feature is its ability to support many microprocessor chips, including the Intel 8085 and 8080, Motorola 6800, Texas Instruments 9900, and Zilog Z-80. The system will support other microprocessors in the future.

In addition to multiple microprocessor support, the 8001 offers three emulation modes for software debugging, partial and full emulation, as well as a real-time prototype analyzer option with all the capabilities of a microprocessor analyzer plus eight channels of external input.

Three Emulation Modes

In a typical design sequence, software is first developed independently using time-sharing, a minicomputer, or some other means. It is then downloaded to the 8001. At this point the in-prototype emulation and software/hardware integration capabilities of the 8001 come into play.

In emulation mode 0, the software runs only on the emulator processor. This enables the program to be debugged on a microprocessor identical to the one that will ultimately be used in the completed product. In emulation modes 1 and 2, the prototype control probe is connected to the emulator processor at one end and plugged into the empty microprocessor socket in prototype circuitry at the other.

Partial emulation (mode 1) lets the user release control in methodical steps from the 8001 to the prototype. The developmental software runs using 8001 memory space and prototype I/O and clock. The 8001 memory mapping feature allows memory to be gradually mapped over to the prototype by address blocks. Throughout partial emulation, the user has access to prototype circuitry via the powerful 8001 debugging system software, which enables him to trace, set breakpoints, examine and change memory and register contents.

Full emulation (mode 2) lets the user exercise the program on the now stand-alone prototype while still maintaining complete control through the Microprocessor Lab. All I/O and timing functions are directed by the prototype; all memory has been mapped over to the prototype; and only the prototype control probe is still in place, emulating the target microprocessor. Although the prototype is effectively freestanding, then, the user may still direct program activity from the Microprocessor Lab.

Hardware Trace Option

The optional real-time prototype analyzer enables the user to dynamically monitor the prototype address bus, data bus, and up to eight other locations on the prototype circuit board. Prototype activity is monitored at full speed, without stopping or slowing up the working microprocessor. This enables the designer to locate critical timing problems and hardware/software sequence problems during partial and full emulation.

In summary, then, each of the three emulation modes supports a specific phase of the product development cycle. Beginning with assembled source language, the designer proceeds from software debugging (mode 0), to the sequential integration of program and circuit (mode 1), to the final integration and test of the stand-alone product (mode 2). The real-time prototype analyzer enhances modes 1 and 2 by allowing the user to monitor and access prototype activity in real time.

8001 CHARACTERISTICS

The 8001 Microprocessor Lab is a modular system whose mainframe houses up to 20 plug-in circuit boards. The system includes System Processor, Debug and Front-Panel I/O, Program Memory, System Communications, and System Memory modules. Also provided are an Emulator Processor module for the microprocessor of choice, its associated prototype control probe, and a ROM-based software module. Additional emulator processor packages are available as options for each microprocessor the system supports. A system terminal is necessary but not supplied.

©IC MASTER 1978

The Real-Time Prototype Analyzer module, additional 16K byte Program Memory modules, and ePROM Programmer modules for the 1702 or 2704/2708 are available as options. Optional peripherals include the TEKTRONIX CT8100 Crt Terminal, CT8101 TTY Terminal, and LP8200 Line Printer.

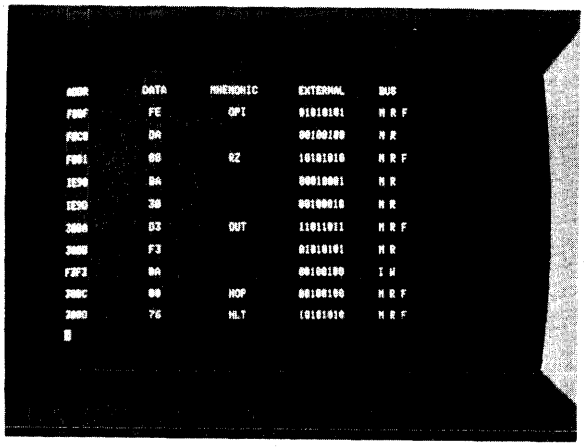
REAL-TIME PROTOTYPE ANALYZER—FUNCTIONAL BLOCK DIAGRAM

©IC MASTER 1978

REAL-TIME PROTOTYPE ANALYZER

The Real-Time Prototype Analyzer, Option 46 for the 8002 and 8001 Microprocessor Labs, is comprised of the Real-Time Trace Module, Data Acquisition Interface, and 8-Channel Data Acquisition Probe. This option provides a real-time trace of the user program executing on the emulator processor, plus eight concurrent channels from any location on the user hardware probe input. The emulator address bus, data bus, control bus, and the eight external signals in the prototype circuit may be monitored without stopping or slowing up the working microprocessor.



The analyzer module is a separate plug-in circuit card that may be inserted into either the 8002 or 8001 System Mainframe. The P6451 Probe connects to the prototype circuitry and permits data transference from the prototype to the analyzer. Data from the prototype is buffered and driven by the probe to the data acquisition interface, and then loaded into the analyzer module's real-time trace buffer.

As the user program is executed by the emulator processor, 48-bit data words are sequentially acquired from the prototype and loaded into the real-time trace buffer. Each data word contains 16-bit data from the address bus; 8-bit or 16-bit data from the data bus; 8-bit data from the test probe; 3-bit data identifying cycle type (read, write, I/O, memory, or instruction fetch); and 5-bit data used internally to identify last start/stop of the emulator. The analyzer will continue to acquire these sequential cycles of logic input until the processor is stopped or the real-time trace buffer is frozen by a specified trigger occurrence. The real-time trace buffer can retain up to 128 data words in pre, variable center, or post trigger modes; thus enabling the storage of pertinent program bus transactions.

A general-purpose delay counter times program execution in clock or event cycles to enable the analysis of critical timing measurements. Count units may be designated as bus instruction fetches, bus cycles, real-time trace stores, microseconds, milliseconds, or any event trigger. As the program executes, the counter keeps track of the number of count units which take place. The current count value may be displayed after the processor is stopped by entering the CNT command from the system terminal.

The Real-Time Prototype Analyzer offers expanded breakpoints to aid in efficient location of prototype problems. Two event comparators located within the analyzer module can be utilized to halt program execution and stop real-time trace. A trigger may be generated on any specific data occurrence in the address bus, data bus, test probe input, and instruction cycle type. Triggering may be immediate; delayed by counting the number of passes; or delayed by counting the number of clock select outputs (clock select may be by microseconds, milliseconds, emulator clocks, etc.). In addition, an output pulse may be generated, via the data acquisition interface, to trigger a logic analyzer or an oscilloscope.

The two event comparators (triggers) may be set to designate a break or halt in the program execution. These comparators may be used as independent breakpoints; or they may be used together to enable a breakpoint on a specific event combination. The program execution can be halted when two trigger events occur simultaneously; when one trigger event precedes another; or when either trigger event occurs. When a break in the program execution takes place, program transactions stored in the real-time trace buffer may be displayed or printed.

Data stored in the real-time trace buffer is displayed sequentially in the order it was acquired from the prototype. Buffer content may be displayed in whole or in part. Optional command parameters are available to limit the storing of data to any specific transaction type, such as memory reads only. If the total buffer contents are displayed, a blank line will separate data sequence associated with each program starting point.

The Real-Time Prototype Analyzer features a convenient and easy-to-understand display format. With this format the address location, data, probe input, and control bus data of each acquired transaction are displayed. If the transaction was an instruction fetch, the instruction is also disassembled into the appropriate memonic readout unique to the emulator type being used.

The Real-Time Prototype Analyzer functions in all emulation modes and operates with all commercial microprocessors supported by the 8002 and 8001 Microprocessor Labs.

REAL-TIME PROTOTYPE ANALYZER CHARACTERISTICS

REAL-TIME TRACE MODULE

ELECTRICAL CHARACTERISTICS

Voltage	Current.
+5.2 V dc	2.4 A typical.
Dissipation	Approx 12.5 W.

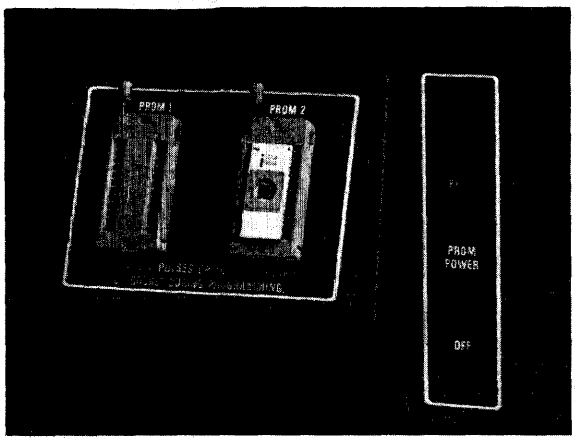
ENVIRONMENTAL CHARACTERISTICS

Ambient Air Temperature	
Operational	0° C to +70°C (+32°F to +158°F)
Storage	−55°C to +80°C (−67°F to +167°F)
Humidity	To 90% relative noncondensing.
Altitude	
Storage	To 50,000 feet max.
Operating	To 15,000 feet max.

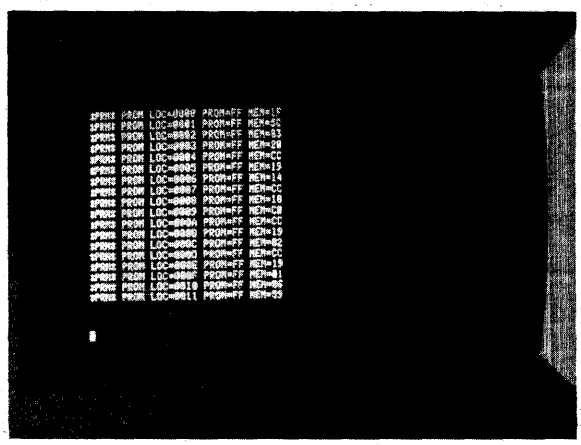
DATA ACQUISITION INTERFACE

ELECTRICAL CHARACTERISTICS

Power	Typical	Max.
+12V dc	20 mA	—
−12V dc	—	400 mA with P6451 Data Acquisition Probe attached. 125 mA without P6451 Data Acquisition Probe.
+5.2 Fdc	—	400 mA
Dissipation	Approx 7 W.	



PHYSICAL CHARACTERISTICS



Dimensions	
Circuit Board	10.5 cm x 12.14 cm (4.09 in x 4.83 in)
Overall Length	12 cm (4.68 in)
Rear Panel	11.2 cm x 6.1 cm (4.36 in x 2.37 in)
Cable Length	50 cm (19.5 in)

INPUT/OUTPUT CHARACTERISTICS

Variable Threshold Range	>+10 V dc to <−10 v dc
Preset TTL Voltage	+1.4 V dc ± 200 mV
Event Trigger Out	High level voltage out (when Vcc = min, Vi = 0.5, Ro = 50 Ω to GND) is >2 V dc.
Adjustments	Variable threshold may be adjusted from >+10 V dc to <−10 V dc with a screwdriver adjustment accessible at the rear panel of the Microprocessor Lab. This voltage must be monitored with a voltmeter having an input impedance of at least 10 MΩ.
Jumpers	With the internal jumper in position '0-3' the clock threshold is designated to be the same as channels 0-3. In position '4-7' the jumper designates the clock threshold to be the same channels 4-7.

©IC MASTER 1978

PROM PROGRAMMER

The 1702 and 2704/2708 PROM Programmer options, each consisting of a circuit card module and supporting software, provide the ability to program either 1702A or 2704/2708 erasable PROM chips. When the module is installed in an 8002 or 8001 Microprocessor Lab mainframe, the PROM Programmer software enables communication between 8001 or 8002 program memory and the PROM installed in the front-panel PROM programming porch.

Before programming the 1702A PROM, all bits are set to 0. Programming is performed by writing Is to selected bits. Address and data are applied to the appropriate pins and each address is cycled through the write sequence until the PROM is completely programmed.

Programming a 2704/2708 PROM is identical to the procedure for the 1702A PROM, except that bit settings are reversed. Programming is accomplished by setting selected bits to 0.

After programming, the PROM can only be erased by exposure to an ultraviolet light source. The transparent PROM cover allows ultraviolet light to reset all bits to their original setting, high or low. The PROM can then be programmed again.

1702A or 2704/2708 PROM Programmer software transfers one data byte at a time, and actual addresses are assigned. Data may be written from 8002 or 8001 program memory (WPROM); read from PROM into program memory (RPROM); or compared on the system terminal (CPROM).

For a write operation (WPROM), the data for each byte to be written is sent to either the 1702 or 2704/2708 PROM Programmer from the program memory module. The PROM Programmer then executes a programming sequence for that byte.

The RPROM command allows the programmed PROM to be read into program memory and dumped onto a console display.

The CPROM compare function performs an address-by-address comparison between the PROM and the program under development. When an inequality between PROM bytes and memory bytes occurs, the memory address, memory byte content, and PROM byte content are displayed on the system console. A successful comparison between designated PROM and memory bytes is indicated by an End of Job message on the console.

1702A PROM PROGRAMMER CHARACTERISTICS

Power	Typical	Maximum
+5 V dc	0.9 A	1.2 A
+12 V dc	60 mA	90 mA
−12 V dc	40 mA	70 mA
50 V ac		0.3 A peak
Dissipation	Approx. 15 W	
Fuses		
50 V ac	0.5 A 250 V located on the rear panel of the Microprocessor Lab	
Adjustments	+47 V dc is adjusted with a potentiometer located on the top edge PROM Programmer module	
Ambient Air Temperature		
Operational	0°C to +70°C (32°F to +158°F).	
Storage	−55°C to +80°C (−67°F to +167°F).	
Humidity	To 90% relative noncondensing.	
Altitude		
Storage	To 50,000 ft max.	
Operating	To 15,000 ft max.	

2704/2708 PROM PROGRAMMER CHARACTERISTICS

Power	Typical	Maximum
+5.2	1.09 A	1.2 A
+12 V dc	36 mA	50 mA
−12 V dc	70 mA	90 mA
30 V ac	68 mA	85 mA
15 V ac	105 mA	150 mA
Dissipation	Approx. 7 W	
Ambient Air Temperature		
Operational	0°C to +70°C (+32°F to +58°F)	
Storage	−55°C to +80°C (−67°F to +167°F)	
Humidity	To 90% relative noncondensing.	
Altitude		
Operating	To 50,000 ft max.	
Storage	To 15,000 ft max.

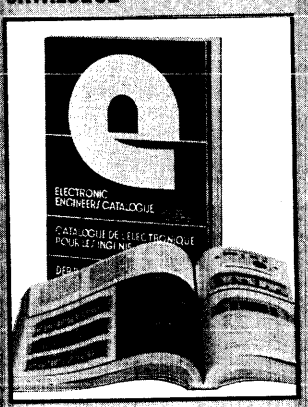
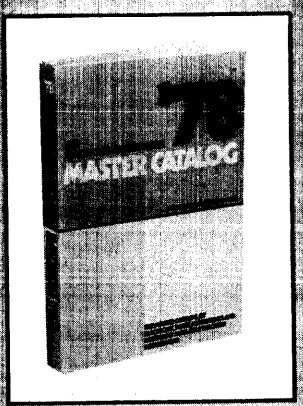
WE KNOW OUR STUFF



40 YEARS OF EXPERIENCE IN CATALOGING, 20 EDITIONS OF eem

eem/ELECTRONIC ENGINEERS MASTER CATALOG—

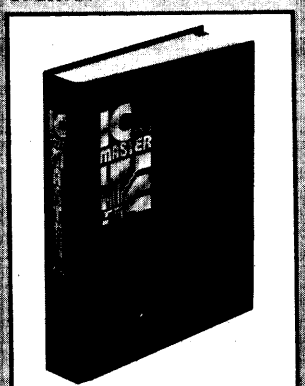


The "blue-ribbon" catalog/directory that has become "the standard of the industry" for electronic engineers, buyers and specifiers.

ELECTRONIC ENGINEERS CATALOGUE

The new catalogue/directory of electronic products available to and from Western Europe and the United Kingdom. Designed especially for the European electronics engineer.

ELECTRONIC DISTRIBUTORS MASTER CATALOG—



(Formerly O-T-S Catalog) The only national catalog designed exclusively for distributors and their customers featuring electronic parts, instruments and equipment.

ELECTRONIC PRODUCTS MAGAZINE—

The products magazine . . . A 100% product-oriented magazine including hundreds of new products and special features every month.

IC MASTER AND THE UPDATES—

The only complete single-source directory including all IC devices manufactured in the United States. Updated three times yearly with accumulative supplements.

eem FILE SYSTEM—

The only filing system designed specially for the electronics engineer. Instant retrieval and organization of data sheets and catalogs.

UTP CUSTOM CATALOGS—

The Cadillac of individualized catalogs for the electronic parts distributor, featuring solely his lines and services.

UNITED COST AND PRICING SERVICES—

The electronic distributors' proven method of being up to the minute on his cost and selling prices.

United Technical Publications, Inc., Div. of Cox Broadcasting Corp., 645 Stewart Ave., Garden City, N.Y. 11530/(516) 222-2500 TWX-510/222-1673

ALTERNATE SOURCE DIRECTORY

The Alternate Source Directory is an industry wide cross reference of those devices which manufacturers claim are pin-for-pin and functional equivalents to IC's made by other firms. It is a compilation of many individual references and shows literally thousands of alternates that aren't implied by their model numbers, especially in the linear and memory areas. Unlike the usual alternate source guides this directory leads you to many alternate sources for any particular device, not just one. It is the most comprehensive alternate source directory ever published and contains over 41,000 cross references.

how to use the alternate source directory

The second column of this Alternate Source Directory shows devices which are replacements for those in the first column. Devices listed in **BOLD FACE** type have technical data in the Master Selection Guide. This information begins on the page listed to the right of the **BOLD FACE** part numbers. Products preceded by a ♦ have been discontinued by the manufacturer. This section does include devices not listed in the Master Selection Guide; e.g., discontinued items, DTL and 54L devices.

This list is compiled from manufacturers' recommendations. Since there is a tendency for every company to only show itself as an alternate to the prominent manufacturers, and for the larger ones to ignore the little ones, not every device is referenced both ways to every other one. Therefore, if you are looking for alternates to a lesser known company's device, take the replacements you find, especially if they are made by prominent companies and look them up to see if you can find any other sources.

In order to maintain this list within some reasonable bounds, the A and B suffixes indicating improved versions generally have been dropped. If this weren't done, for example, every higher speed selection conjured up by a memory manufacturer would result in a device that could replace many equal or slower competitors and this directory would become highly involved in slight performance variations. Moreover, improved performance is only important if your circuits take advantage of it.

One of the difficulties with any cross reference is that devices meant to be alternates do not necessarily perform the same in all circuits. Thus, it will be necessary for you to check specifications, or even to check circuit performance before deciding which alternates are right for you. A major benefit of this list is that it gives you more alternatives to study. But if you don't find what you need here, it may be possible to find additional alternates by locating the device in the Master Selection Guide. Particularly for digital circuits, the other products grouped with it will normally offer similar or identical performance.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements. Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

Fairchild (cont'd)

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

◆ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.

National Semiconductor (cont'd)

♦ Discontinued

The manufacturers report their devices can be used as direct replacements.
Performance details often differ, so compare the specifications considering your requirements.
